

THE
TROPICAL
AGRICULTURIST.

ES. 2,016

Spencer & Co.,

MADRAS, BANGALORE AND OOTACAMUND.

Our New Registered Brand.

FLOR DE SUMATRA.

Our New Registered Brand.

OUR CIGAR FACTORY at TRICHINOPOLY is now under the personal supervision of a gentleman of many years' experience both in the cultivation of Tobacco and the manufacture of Cigars, and we are devoting our best exertions to the manufacture of a class of Cigars, superior both in quality and appearance to those that have long been known throughout India as Trichinopoly Cheroots.

EXPERIENCE has shown that a mixture of Sumatra leaf with the best Dindigul Tobacco produces a blend which, while preserving the qualities of both descriptions, is in many respects, superior to either, when manufactured separately.

We have the pleasure to announce that we have succeeded in securing a large supply of the best Sumatra leaf procurable of the present season's crop, and have every reason to anticipate that we will be able to supply Cigars during the coming season superior to any that have hitherto been known in India.

"SALISBURYS" R. A.

Havannah-shaped, 6 inches long, in Cedar-wood boxes of 50...Price per box ... 2 8
200 can be sent to any Railway Station in India, for R1 Railway charge.

"IMPERIALS" R. A.

Havannah-shaped, 4 $\frac{3}{4}$ inches long, rather thicker than "Salisburys," put up in boxes of 50 ... Per box. 2 0
Five boxes can be sent to any Railway Station in India for R1 Railway charge.

"LITTLE RANDOLPHS" R. A.

Manilla-shaped; about 3 $\frac{1}{2}$ inches long, put up in boxes of 100...Per box ... 2 0
Five boxes can be sent to any Railway Station in India for R1 Railway charge.

"MAYOS" R. A.

Manilla-shaped, 4 $\frac{3}{4}$ inches long, Per box of 100 ... 3 8
Three boxes can be sent to any Railway Station in India for R1 Railway charge.

"BEACONSFIELDS" R. A.

Are manufactured in three sizes, put up in Cedar-Wood boxes of 100.

No. 1 about 4 $\frac{1}{2}$ inches long...Per box...3 0
No. 2 " 4 " ... " ...2 12
No. 3 " 3 $\frac{1}{2}$ " (thin) " ...2 8

The following quantities of each can be sent to any Railway Station in India for R1 Railway charge.

3 Boxes of No. 1. 4 Boxes of either No. 2 or 3.

We also Manufacture the following from selected Dindigul Tobacco:—

"GOLD MOHURS" Nos. 1 AND 2, "SIESTAS" Nos. 1 AND 2,
"LARRANAGAS."

All orders should be addressed

SOLE AGENTS IN CEYLON:

MESSRS. MILLER & CO.

DAVIDSON'S PATENT SIROCCO TEA DRIERS.

OVER 2,200 NOW IN USE.

Illustration of Down-draft Sirocco.

Dries tea leaf in eight minutes, with pure hot air, at 240° F., at which temperature this very rapid rate of drying produces the highest quality of tea obtainable from the leaf used.

A powerful suction fan draws the hot air down through the tea with a speed and force equal to that of a high gale of wind, and the operating principle and construction of the "Down-draft Sirocco" are such that, notwithstanding the great strength of this air-blast, the tea does not get disturbed, or whirled about on the trays when in the Drying Chamber, nor blown off them being inserted or withdrawn through the tray-ports.

The leaf is exposed to the hot air on wire-web trays, ten of which fill the Drying chamber. The trays, filled with the damp leaf, are put in through the lower, or inlet tray-port, and a strong and easily worked mechanical lift moves all the trays upwards to the outlet port, where the finished tea is withdrawn. One movement of a hand-lever works the lift, and simultaneously opens or closes the door of the inlet tray-port, and inversely operates the throttle valve of the fan, whereby, when the tray-port door is open, the fan valve is closed, and *vice versa*. By this arrangement the trays can be inserted in calm air; but when the tray-port door is closed the fan again acts on the trays with its full suction-power.

The Apparatus works on ground level, neither pit nor platform being required, and when set upon a layer of tiles or bricks, it can be worked as easily on a loft as on a ground floor. The air is heated by our new patent cast-iron flue "Sirocco" Stove, the construction of which is very strong and durable. Any fuel may be used, and about 80 lbs. of wood or 40 lbs. of good coal will dry each 100 lbs. of tea.

The "Down-draft Sirocco" is easily erected. The principal working parts are sent in made-up sections, and merely require to be bolted together to form the complete machine, which, when erected, is 7 feet high and occupies a floor-space of only 6 feet by 12 feet.

Reports on the Working of the "Down-draft Sirocco".

The working of the "Down-draft Sirocco" has been thoroughly tested during the past season, and detailed and authenticated reports have been furnished of trials which were made with it on different Estates in Assam, Cachar, Sylhet, Darjeeling, Doonar, Ceylon, and Java. These reports show an average output of 145 lbs. dried tea per hour; with 100 lbs. per hour of ordinary wood fuel.

Brokers' reports have in every instance been in favour of the "Down-draft" teas, to the extent of 1d to 2d per lb. on the medium, and as much as 4d to 6d per lb. on the fine quality, as compared against teas manufactured in other driers from the same lots of leaf and at the same time and place. Some of the "Down-draft Teas" to which the above reports refer were dried in the unprecedentedly short time of four minutes.

For the final firing of tea before packing the practical working of the "Down-draft Sirocco" has also given the greatest satisfaction. It finished off Pekoes and Souchongs at the rate of 8 maunds per hour, and Broken at 5 to 6 maunds per hour.

For this season we are also making a considerably larger size machine than that with which the above results were obtained, and this larger machine is calculated to dry 160 lbs. of tea per hour, with 130 lbs ordinary wood fuel.

This machine will be fitted with a larger and more powerful fan, whereby the strength of air-draft will be further increased, a more paid rate of drying effected, and a still higher quality of tea turned out.

N. B.—As the "Down-draft Sirocco" has been found to increase the value of the teas dried in it to the extent of an average of fully 2d per lb. as compared with teas dried in the ordinary way, it will be readily seen that by the enhanced prices thus obtained, two or three weeks' working of a machine would repay its whole cost.

Prices of the new enlarged "Down-draft Sirocco" complete with countershaft and hangers, change pulleys, 12 trays, thermometer, &c., £150 f. o. b. outward steamer at Liverpool or Glasgow. Owing to the advances in the price of iron and steel which have taken place during the past few months, the price of the smaller sized "Down-draft" (same as that in use during the past year, and the size to which the above quoted reports refer) is now £130 (former price £120.) Terms.—Cash against documents.

SELF-ACTING UP-DRAFT SIROCCOS.

The self-acting "Up-draft Siroccos" dry tea with a self-acting current of hot Pure Air, neither fan, nor any form of mechanical air propeller being required to create the air draft, which is produced entirely by the action of the "Sirocco" Stove, wherein any description of fuel may be used—wood, coal, patent compressed coal, bamboo, ekur, grass, &c.

Working with this natural up-draft of air at a temperature of 240° F. the tea is dried in twenty-five to thirty minutes. The waste hot air from the apparatus, when in work, is useful for withering green leaf, when the leaf rooms are suitably arranged for this purpose on the upper floor of the tea-house.

The new patent cast-iron fire Stove introduced with our "Down-draft Sirocco" has been so highly satisfactory in its operations that we are now embodying the same design of Stove with all sizes of our "Up-draft Siroccos" for this season. Their efficiency and durability will be thereby greatly increased, as these Stoves are much stronger and heavier, and have a larger fire-place for the more economical combustion of the fuel. An Air-duct will also be fitted to these machines directly over the trays which will enable all the hot air to be carried into the withering loft above or right out of the tea house. These Air-ducts will increase the air current up through the tea effecting considerable increase in the tea output and a saving in fuel consumption.

The Prices and Capacity of the "Up-draft Siroccos" are as follows:—

No. 1 Sirocco, original make (with large air chimney) Drying about 40 lbs. Tea per hour, Price, £80	Each complete with Trays, Thermometer, Fire Irons, &c., &c., packed and delivered f. o. b. outward steamers at Brixenhead or Glasgow.
Side-drawer, 4-Tray, with 2 extra Trays, Drying about 35 lbs. Tea per hour, Price, £75

BETTS' PATENT IMPROVED INCORRODIBLE TEA LEAD.

BRAND.

BRAND.

This article will be found greatly superior to the ordinary Rolled Lead, combining advantages as an hermetic metallic envelope for Tea.

The Tin surface prevents oxidation or change of color from the effects of climate, and with the Body of Metal beneath forms a kind of Solder when in contact with the Soldering Iron, which materially assists the workmen in securing an air-tight seam or joint. The Metal is pliable, tough, exceedingly close in grain, and free from holes.

STRATFORD, LONDON, E.

**DR. J. COLLIS BROWNE'S CHLORODYNE,
THE ORIGINAL AND ONLY GENUINE.**

Chlorodyne is admitted by the Profession to be the most wonderful and valuable remedy ever discovered.
Chlorodyne is the best remedy known for Coughs, Consumption, Bronchitis, Asthma,
Chlorodyne effectually checks and arrests those too often fatal diseases—Diphtheria, Fever, Group, Ague.
Chlorodyne acts like a charm in Diarrhoea, and is the only Specific in Cholera and Dysentery.
Chlorodyne effectually cuts short all attacks of Epilepsy, Hysteria, Palpitation and Spasms.
Chlorodyne is the only palliative in Neuralgia, Rheumatism, Gout, Cancer, Toothache, Meningitis, &c.

From Lord FRANCIS CONYNHAM, Mount Charles, Donegal, 11th December, 1868.

"Lord Francis Conynham, who this time last year bought some of Dr. J. Collis Browne's Chlorodyne from Mr. Davenport, has found it a most wonderful medicine, will be glad to have a half-a-dozen bottles sent at once to the above address."

"Earl Russell communicated to the College of Physicians that he has received a despatch from Her Majesty's Consul at Manila, to the effect that Cholera has been raging fearfully, and that the ONLY remedy of any service was CHLORODYNE."—See *Lancet*. 1st December, 1864.

CAUTION.—BEWARE OF PIRACY & IMITATIONS.

CAUTION. "Vice-Chancellor Sir W. Page Wood states that Dr. J. Collis Browne was undoubtedly the inventor of CHLORODYNE; that the story of Defendant Freeman was deliberately untrue, which, he regretted to say, had been sworn to."—See *Times*. 10th July, 1854.

Sold in Bottles, 1s. 1/4, 2s. 9d., 4s. 6d., and 11s. each. None is genuine without the words "DR. J. COLLIS BROWNE'S CHLORODYNE" on the Government Stamp. Overwhelming Medical Testimony accompanies each Bottle. Sole Manufacturer—J. T. DAVENPORT, 33, Great Russell Street, Bloomsbury, London.

BROWN, RAE & CO.'S

(PATENT)

TEA SIFTING MACHINE.

40 MACHINES SOLD IN CEYLON IN 12 MONTHS.

THE ADVANTAGES THIS SIFTER POSSESSES OVER ALL OTHERS ARE

IT DOES NOT GREY THE TEA.
 IT IS ALMOST NOISELESS.
 THE SIEVES ARE INTERCHANGEABLE.
 THE GRADING CAN BE ALTERED AT WILL.
 AND
 IT IS THE CHEAPEST IN THE MARKET.

We have received numerous Testimonials, but the rapid sale the Sifter is having is ample evidence of its efficiency. To show what can be done with the Machine, we extract the following from a letter lately received:—"I am still as well pleased as ever with the Sifter, and have just done 748 lb. in 50 minutes."

Price R400 complete.

ORDERS EXECUTED ACCORDING TO PRIORITY OF RECEIPT.

THE "PLANTERS" ROLL-BREAKER.

(SOUTER'S PATENT.)

THIS MACHINE continues to give complete satisfaction, and we are in receipt of most favourable accounts of its working in every case where we have supplied it. We extract the following from various Testimonials:—

"It does its work in every respect well and quickly. We put 640 lb. of roll through in 10 minutes."

"I must say it is the best Machine of its kind that I have seen; it breaks up a fill of the Excelesior in about 3 or 4 minutes."

"I have been working the ROLL BREAKER for some little time now, and am much pleased with it. A roll of the large Rapid is broken easily in 4 minutes, and the work is well done."

"I enclose cheque for the Roll Breaker: it does its work A. 1."

Price R150, or, combined with Roll Sifter, R275.

TO OUR READERS.

In closing the Ninth Volume of the "Tropical Agriculturist," we would once more direct attention to the large amount of useful information afforded and to the great variety of topics treated in our pages. From month to month, we have endeavoured to embody in these pages the latest results of practical experience and scientific teaching in all that concerns tropical agriculture; and our ambition has been to make this periodical not only indispensable to the planter, but of service to business men and capitalists, never forgetting that agriculture trenches upon every department of human knowledge, beside being the basis of personal and communal wealth.

While directing our attention chiefly to the products prominently mentioned on our title-page, we have always taken care to notice minor industries likely to fit in with sub-tropical conditions; and our readers have an ample guarantee in the pages before them, that, in the future, no pains will be spared to bring together all available information both from the West and East, the same being examined in the light of the teachings of commonsense as well as of prolonged tropical experience in this, the leading Crown and Planting Colony of the British Empire.

A full and accurate Index affords the means of ready reference to every subject treated in this, the ninth volume, which we now place in our subscribers' hands, in full confidence that it will be received with an amount of approval, at least equal to that which has been so kindly extended to its predecessors.

We are convinced that no more suitable or useful gift can be made to the tropical planter or agriculturist, whether he be about to enter on his career, or with many years of experience behind him; than the nine volumes of our periodical which we have now made available. They are full of information bearing on every department and relating to nearly every product within the scope of sub-tropical industry.

In conclusion, we have to tender our thanks to readers and contributors, and our wish that all friends may continue to write instructively and to read with approval; for then, indeed, must the "Tropical Agriculturist" continue to do well.

A. M. & J. FERGUSON.

THE TROPICAL AGRICULTURIST MONTHLY.

Vol. IX.]

COLOMBO, JULY 1ST, 1889.

[No. 1

BARK FOR TANNING: THE BLACK WATTLE: A NEW INDUSTRY?

WE call attention to the letter of Mr. Tringham and the commercial report accompanying it on page 865, Vol. VIII. The information is not so full as we should like, but it is sufficient to be very sugges-

tive of a "good thing" in cultivation. At 4 feet apart every way, Mr. Tringham could have 2,700 trees of *Acacia decurrens* (otherwise known as black wattle) to the acre. These yielded $\frac{1}{2}$ cwt. of bark per tree at $3\frac{1}{2}$ years old, or $\frac{3}{4}$ tons per acre valued as per sample in London at £10 to £11 per ton. Surely there is margin enough here for a profitable industry? Mr. Tringham should give us some idea of his outlay in planting and harvesting, though very likely his experiment was on so small a scale as scarcely to afford a fair criterion of what 20, 50 or 100 acres would do? Though spoken of as "mimosa bark," it is well known that *A. decurrens* with its rapid and enormous growth is very different from the ordinary mimosas of our hedgerows in the lowcountry. The mimosa genus at one time included nearly a thousand different species. The Australian acacias are huge trees, while the tropical mimosas are little more than shrubs. The most common tanning bark in use in India is that of *Acacia arabica* or "the babul bark," and as much as "222 cwt. of tanners' bark" were exported in 1887 from Ceylon to British and French India; but from what description of tree this was taken, the Customs Report gives no hint. On the other hand, we learned from Mr. Vincent's Forest Report that the "Valem Bark" exported to India from the Northern Province was got from *Acacia eucophlea* and was used in India in arrack distilleries. In 1887 as much as 960 cwt. of this bark were sent from the Northern Province. Is it used in any of the Ceylon distilleries?

In Australia, the bark next the Black Wattle most commonly used for tanning is that of the *Acacia melanoxylon*, one of the most successful in growth and most valuable for timber purposes of any Australian trees growing on our hill country. It is also a very rapid grower, spreading from the root, as may be seen in several gardens and plots of land about Nuwara Eliya, though it is not so troublesome in this respect as Mr. Tringham's *Acacia decurrens* (black wattle). The point for practical men, however, is, which is the more profitable tree to cultivate? Both are rapid growers for bark, and the value for tanning purposes of the product will be much about the same? But we suspect the Black Wattle from the figures given by Mr. Tringham must be first in the race. On the other hand, there may be a question about the value of the respective timbers. On this point, Mr. Tringham gives us no information, although we suppose the timber of the wattle trees at $3\frac{1}{2}$ years old must have been of value other than for firewood? As regards the *melanoxylon*, the blackwood of Australia, its wood is hard and durable, the heartwood being dark brown and beautifully mottled, soft, shining and even-grained, conspicuously marked on a vertical section. In Australia this timber is used for cabinet work, coach building, railway carriages, &c.; but in the Nilgiris, curiously enough, it is neglected and thought only fit for firewood. The late Rev. W. Oakley showed us a bookcase made of the wood of *A. melanoxylon* which was not only hard and substantial, but beautifully marked, so as to be superior to nadoon, and almost equal in appearance to calamander. Both the *Acacias* (*decurrens* or black wattle and *melanoxylon* or black wood) are clearly worth cultivating especially in our higher regions. Mr. Tringham will no doubt give the preference to the black wattle, and if tanning bark be the object in view, it is apparently, the best. If indeed, 30 tons of bark can be taken off an acre of land after four years' growth of this tree from seed, and the same be worth £300 laid down in London, while the timber is useful as fuel if nothing else, not a few of our planters we should think will go in for planting their reserves with black wattle (*Acacia decurrens*). But let them be careful by a big trench or ditch around the wattle reserve, to prevent the roots passing into their tea or cinchona fields. The question we should like Mr. Tringham now to answer is what outlay per acre may be estimated against the £300 gross return? It seems to us that even taking an outside figure, the margin left would be wide enough to provoke a planting rush into "wattles"! But then, the other ques-

tion has to be faced of overdoing the market as with so many other products and reducing the price from £10 to perhaps £5, £2 or even £1 per ton! "Ay, there's the rub!" There is "the dread of something after"—the inevitable drop in prices, when the harvest is ready to reap, which the Ceylon planter has had so often to face. Nevertheless, so far as we know there is a large and growing demand for tanning barks and the area suited to growing black wattle or black wood in Ceylon is limited in extent, more particularly now that the official rule about selling no more Crown land above 5,000 feet elevation, is enforced. We think therefore that there is some reason for encouraging planting experiments after the example set by Mr. Tringham.

◆

**AN ENGLISH RUBY COMPANY FOR BURMA ;
—WHY NOT A LONDON GEM COMPANY
FOR CEYLON?—No. II.**

SURPLUS WEALTH AND SPECULATION—RUBY MINING IN BURMA AND THE DIFFICULTIES TO BE ENCOUNTERED —CEYLON SAPPHIRES AND OTHER PRECIOUS STONES —CEYLON A BETTER FIELD FOR GEM MINING THAN BURMA—BETTER PROTECTION OF LIFE AND PROPERTY —EASY TRANSPORT AND CHEAP LABOUR AND CERTAINTY OF SUCCESS—CHIEF CENTRES OF GEMMING OPERATIONS IN CEYLON.

One of the most prolific sources of instruction as well as amusement to a philosophic mind is without doubt a watchful observation of the popular investments in which from time to time the capitalists of Europe employ their surplus wealth. Surplus wealth in reality it may be said to be, for whilst in all ventures and speculations of this kind there undoubtedly can be found men, who, attracted by some special condition such as the prospect of extraordinary returns or more commonly perhaps by a spirit of excitement and adventure, make investment to the utmost of their means, still the majority of subscribers to these ventures are those who possess unemployed capital, and to whom the absolute loss of what they invest would not by any means signify ruin or disaster. It would seem that it only requires the presence of some notion by which the fancy of the moneyed public can be tickled, no matter how absurd or dangerous the scheme may appear to be to the outside public, and forthwith wealth and capital is forthcoming in tens and hundreds of thousands of pounds for the formation of companies, or the establishment of industries, by which the subscribers are to change their tens for twenties, their hundreds for thousands. When once the mania has been fairly established there appears to be no visible limit to speculation and gambling, until either success or disaster put an end to the excitement, which gradually dies away and for a time gives place to an uneasy slumber which continues to pervade the financial atmosphere until it is once more aroused to activity by some fresh and taking attraction.

Many of these objects of popular excitement are no doubt sound commercial undertakings and perfectly legitimate in their ends: for instance the conversion of the world-famed breweries at Burton and in Dublin into limited companies. Many on the other hand are mere visionary propositions, with no past history on which to build a reasonable prospectus—speculations in every sense of the word. One of the most notable of these public schemes during recent years has been the creation of the Company for working the Ruby Mines in Upper Burma. The extraordinary rush for shares in the proposed Company, by the capitalists of England

and the Continent, is too recent a matter to need more than the merest mention here, but there are a variety of circumstances in this connection which claim attention and which apparently have been either altogether ignored, or not deemed worthy of second thought, but of which a more intimate knowledge and more careful examination might very possibly have exercised considerable influence on the minds of the subscribers to the scheme. In all probability all that was known about it by the majority of that section of the public who so wildly tendered their capital, was simply that from time to time they had seen rubies which ostensibly were obtained in Burma. They were told of rich mines belonging to the King of Upper Burma, from which rubies of large size and the finest quality were obtained and reserved for the royal use, and of which large stores was supposed to be hidden away in the coffers of the palace at Mandalay. At any rate this was the belief of some of those who knew that Messrs. Streeter and Company, a world-famed firm of jewellers, for a very considerable money payment had obtained from the British Government a concession to work these mines as a monopoly, and it was not likely they would have done such a thing without "there being something in it." The remainder—probably the greater proportion—of the subscribers heard it was likely "to be a good thing," and seeing their neighbours join were eager to take their share of what might be going. And so with great flourish of trumpets, the Company was floated, and what may result remains to be seen in course of time. Very few indeed of those who wildly contended for shares took the trouble of making searching inquiry into the exact nature of the undertaking in which they were embarking, the position of the mines, the distance from a civilized centre, the dangers of working in a newly-conquered country far from pacificated, and to all appearance not likely to be so for many years to come, and where at the present time no person can travel in safety even along the public roads without an armed escort of police, and where murders and dacoities are of daily occurrence. How many of them took into consideration the extreme difficulty that would have to be faced in the transport of machinery and supplies over lengthened distances in a hostile and unhealthy country to an elevation of some 4,500 feet above sea-level, and which when once erected must be guarded by night and by day by a large force of armed police? How many of them ever had the means of being assured that the King of Mandalay had this much talked-of wealth in rubies, and, if he had, that they were obtained from the one small spot of land known as the ruby mines, when thousands of square miles along the range of the Shan hills were equally as likely to contain rubies in just as great abundance? How many indeed of these subscribers ever heard or thought of these facts—for facts they are and not by any means the emanations of a vivid imagination? It is probable that had they considered these facts many would indeed have paused to consider whether the game was worth the candle, and whether it was not possible for them to venture their money on a somewhat similar undertaking in some other country without increasing a tithe of the risk and danger to life and property they were courting so recklessly when they selected Upper Burma as the scene of their speculation. Had they done so there would have been no necessity for extended search or lengthened inquiry to acquire the knowledge that there are other localities quite as famous as Burma for the production of gems—and gems in greater variety and enhanced value. They would soon have learned that Ceylon from time imme-

morial has been the most famous gem-producing country on the face of the globe. The sapphires of Ceylon are thus described by Mr. E. W. Streeter:—"Sapphires are azure blue, indigo, dark red colour, violet blue, poppy red, cochineal, carmine, rose red to rose white, milk white, yellow white, French white, lemon colour, and green. As a rule the colours are pure and high. Sometimes a crystal is found exhibiting a variety of colours. The asteria or star sapphire shows under the microscope thread like shafts directed towards the faces of the six-sided prisms, and it is the reflection of light from these which give to the stone its star-like brilliancy. The blue variety is called sapphire in its limited sense. The red variety is the ruby." The above would seem sufficient to attract the attention of would-be subscribers to a venture in gemming mines, but they are in reality hardly a moiety of the riches which our far-famed island offers in profusion to those who should be wise enough to search for them. The list of Ceylon gems is long and complicated:—rubies, sapphires, corundum and diamond spar, pleonaste, catseye, star stones, garnet, carbuncle, jacinth, cinnamon stone, topaz, &c.

Here is wealth of gems indeed for picking up, wealth in abundance lying hidden almost on the surface of the ground, wealth of gems to be had—so to speak—for the asking, without difficulty and without danger, and in a civilized country that has been settled under British rule for close upon a century. Why then should the capitalists of Europe go to Burma and leave Ceylon gems to "blush unseen"? Even now why not a Ceylon Gem Mining Company as well as a Burma Ruby Mining Company. It surely needs but little in the way of demonstration to prove that such a company is certain to be a very handsome investment. The preliminary expenses would be very light compared with those that must of necessity be incurred in Burma, and the difficulties so serious in the latter country would be a mere trifle as regards Ceylon. In the first place machinery and supplies could be carried in perfect safety, and the works initiated in any part of Ceylon without fear of attack. Whereas in the Burma ruby mine district every man walks in fear and trembling, literally carrying his life in his hand. Neither can he lie down to sleep with the assurance that his house will not be burnt over his head during the night and his life endangered when endeavoring to escape. Such danger need not even be dreamt of in this peaceful country. Again, as regards the difficulty of transport, the route in Burma is either 800 miles—*eight hundred miles!*—by water and then one hundred more across a dried up unhealthy country to the foot of the hills, and from thence up steep, precipitous, broken tracks to the enormous elevation of over 4,000 feet. Or it must run 400 miles! by a railway (at present very imperfect and certain for some years to come to be damaged by floods in the rainy season), then one hundred miles by water, and the rest of the distance as described above, to the top of the hills or at any rate half-way up those that reach 7,000 to 8,000 feet. Now let us see what would be done in Ceylon. Take Ratnapura—the city of rubies in the native tongue—as at present the centre of the gemming operations. We have about 60 miles only of good cart road—and *that is all*, or we may take the alternate route via Kalutara, where we have 35 miles of railway and say 70 of good water carriage—and we are at Ratnapura. The transport of material and supplies is thus plainly shown in Ceylon to be a mere fraction of what it is in Burma; and as for further progress, the island possesses the finest roads of any

hill country in the world, those from Ratnapura reaching to Pelmadulla and Balangoda on the one side, to Rakwana and Morowak Korale on the south, and Nambapana and the sea on the west,—the whole of the intermediate country being one vast bed of gem-producing soil. Nor need we rest content with even this enormous stretch of country, for some of the finest stones have been found in the southernmost portions of the island, served by fine well-preserved roads, and the Ginganga. As regards labor, the condition of the inhabitants in Upper Burma is such, that almost the entire force of labour employed by the Ruby Mining Company will have to be imported, principally from India; whilst the protecting force will in all probability be armed Madraseses, or perhaps Goorkhas from Nepal. What the cost of such labour may be, it is impossible to state, but by the time that all the expenses of introduction and teaching, the loss of advances consequent on death by disease and violence, the cost of a medical staff, and payment for protection, are all totalled up,—the cost per head for each day's labour will be something enormous, sufficient to startle most Ceylon men out of their usual equanimity. Whereas in Ceylon the labour force is resident on the spot, a force accustomed to the work and climate, requiring no advances and no attendance—and obtainable at very cheap rate of wages. This should in itself be a sufficient inducement for Ceylon gemming to take preference over that of Burma or any part of the world. All engineers, road officers, planters and other men of experience in working large numbers of men in the East cannot but admit that their work loses almost all its difficulty and an immense proportion of its cost, when executed by a labour force at once acclimatized to the country and accustomed to the work, and such a force would be at the disposal of any mining company that seeks Ceylon as the scene of its operations. Again there is the element of uncertainty which so largely pervades the Burma Company's operations and which is altogether absent from any such that may be undertaken in Ceylon. It is by no means certain that King Theebaw really possessed a hoard of magnificent rubies such as has been represented. So large an amount of tinsel of all descriptions was found in the palace and the famous pagodas at Mandalay that considerable suspicion was raised whether any large proportions of the reputed wealth in gems possessed by the king was really of any value whatever. In any case, if it really existed, much of it most mysteriously disappeared at the annexation of the country. But suppose this immense value of gems did in reality exist, how do we know that it was extracted from that one little spot of ground known as the ruby mines, and if it was so extracted are not the probabilities in favour of its being already exhausted and little or nothing of value remaining for further working? Again suppose that the whole of the country along the Shan Hills should turn out to be gemmiferous, other companies or private parties who have not paid an immense premium for the concession of working have a better chance by far in making mining operations a paying concern and underselling the present Company. On the other hand Ceylon has no *modern* tale to tell of fabulous stores of hoarded gems, but, in place of such creations of fancy and imagination, it can point to what can be seen every day—and what could have been seen at any time these hundred years past, a steady production of valuable gems, being continually thrown on the market as the result of merely sinking little pits a few feet in depth, here and there over the

land, as fancy dictate to the indigenous population of the country. It is indeed surprising that during almost a century that has elapsed since the Dutch were ousted from the possession of Ceylon, nothing systematic in the way of extracting the mineral wealth of the island has ever been attempted by those whose lives have been spent there in the endeavour to attain fortune and position. Isolated cases there have been—as is well-known to old residents—where Europeans have found it amply remunerative to employ their time in searching for precious stones, and native speculators have from time to time obtained extremely lucrative results from such operations, but up to this time they have never been attempted on an extended scale, such as would be made by a powerful syndicate which could afford to equip a really effective prospecting party, which should thoroughly examine the country, and determine the actual capabilities of the different districts which have already—on a small scale—afforded such satisfactory returns.

Such a state of “masterly inactivity” can surely be no longer tolerated. With untold wealth actually lying at our feet, it will not be in accordance with the traditions of a great mercantile nation like England to allow it to remain unsought and untouched as it has been all too long already. It may confidently be foretold that before many more months have passed over our heads we shall be in a position to show that Ceylon will hold the same pre-eminence in offering its store of precious gems to wealth and beauty throughout the universe as it has hitherto held pre-eminence in all other ventures which it has ever undertaken.

PLANTING ON THE CONGO.

From a report of the Belgian Consul-General in the Congo State, it appears that the efforts made to introduce European vegetables and fruits in that district have been rewarded with very great success. The Government has imported tobacco-seed from Havana and Sumatra, which is cultivated in conjunction with native tobacco. The natives cultivate tobacco badly, but efforts are being made by the Government to teach them better methods. The inhabitants of the Lower Congo have been very successful in cultivating not only the usual African products, such as manioc, sweet potato, &c., but also sorghum, maize, and the “wandu” haricot, called “Boma” by the natives. The cotton-plant grows in its wild state, and the natives manufacture from it hats, wallets &c. No effort has yet been made to cultivate it for trade purposes.—*Nature*, April 25th.

A FAMOUS DIAMOND.

The fictions which have so long circulated about the famous diamond which Thomas Pitt sold to the Regent Orleans, impart a peculiar interest to the work just issued by the Hakluyt Society, in which, for the first time, the facts of the case are told with the minute historical accuracy to have been expected from the learned editor of the volume. The circumstances under which a private Association for the printing of old works of travel came to concern itself with Pitt and his gem are in themselves almost romantic. Many years ago Mr. Barlow found, among the rubbish of a Canterbury bookseller's shop, a musty old manuscript, which turned out to be the Diary of Sir William Hedges, who, during the years 1681 to 1687, played a notable part in India as the first Governor and Agent of the Bengal Factories. How it came there is not known. But, no doubt, like the curious Diary of Richard Cocks, of the English Factory in Japan, also issued by the Hakluyt Society, it formed part

of some five hundred tons of “worthless” manuscripts which thirty years ago were ordered to be removed from the India Office and sold as waste paper. The history of the gentleman, the grandfather of the great Earl of Chatham, and the ancestor of more than one illustrious House, whose name is inseparably associated with the Pitt diamond, has hitherto been rather obscure. He seems to have first appeared on the Indian Coast as the captain of a trading vessel, or “interloper,” as the merchants who defied the monopoly of the Company were termed. So audacious did he become, that the Company, with a worldly wisdom which never deserted them, bought off his opposition, by making him Governor of Fort St. George, then their chief settlement in Madras. In this capacity he accumulated enormous wealth, and, returning to England in 1711, played the typical Nabob by buying estates and rotten boroughs, giving great dinners, marrying his sons and daughters into great families, and obtaining places for his relatives; returning himself as one of the members for Old Sarum, which he owned, and getting the lucrative post of governing Jamaica, though it does not appear that he ever took up the office. Altogether, this choleric factor seems to have led a stirring life of sixty-four years, and to have inspired, both in India and out of it, a great deal of that violent enmity which is often the surest test of a determined character. But of all his acts—commercial and political—his purchase and sale of the great diamond is the one which is destined to live longest in public memory. Like most of the Company's factors, Pitt enriched himself by private traffic, and diamonds seems to have formed his favourite ventures. He was constantly sending home stones to his London agents, and the bulk of his early correspondence is occupied with the quaintly-spelt praises of these gems “without fowles.” It was in 1701 that he first wrote about the historic stone, enclosing a model of it to Sir Stephen Evance, though owing to the price asked for it—two hundred thousand pagodas—he expressed no immediate intention of buying it. Nor did his correspondent offer any encouragement, since diamonds were at that time not rapidly saleable, as “wee are now gott into a Warr, and the French King has his hands and heart full soe he cant buy such a Stone, and there is noe Prince in Europe can buy itt.” But the “excellent cristalline without any fowles” was too much for Pitt's indifference. For in 1702 it was purchased and sent home by him in charge of his son Robert, on board the “Loyal Cooke,” which left Madras in October, 1702.

From that day his troubles seem to have begun. His correspondence is interminable, and the burden of it “ye stone.” He is in terror—on account of the diamond—lest the ship be lost or taken by “pyrats,” and in London he is anxious about thieves, fire, and the failure of his agents. To Mr. De Ffonseca he suggests that the King of “France or Spaine” would be “the likeliest chapmen for it, unless our Parliament, upon good success in some noble undertaking, will be Soe Generous as to buy it for the Crown of England.” But on no condition is it to be parted with for less than fifteen hundred pounds a carat. He is always harping on some Sovereign purchasing it, either immediately or after the “Warr, to which God send a happy and speedy conclusion; since then he tells his agent, “you'le have chapmen enough for it, for Princess generally covet Such Jewells.” By-and-by gets doubtful whether his son is attending to his business, and cautions Sir Stephen Evance to see that, if some “foreign Prince”

buys it, the messenger receives. "noe money on that account in a foreign Country, for fear they Strip him of it before he gets out of it." Soon he becomes suspicious that he is being cheated in the cutting, the pieces sawn off being valued at so much less than he had hoped. Next he hints that "if we are lucky to put Charles on the throne of Spaine, I know nothing he can purchase to make his acknowledgments to our Queen so acceptable" as "the diamond," but he reiterates his resolve never to sell it for less than fifteen hundred pounds the carat. Sir Stephen Evance next falls under his ban, and John Dolben is the repository of his hopes and fears and anxieties. He hears that, upon the Union with Scotland, it is proposed to "present the Queen with the Royall title of Empress." If so, "the diamond" is assuredly the proper gift for the occasion. But fifteen hundred pounds a carat is his figure, and at that, he adds, with more vigour than truth, it is "as cheap as Neck beef," and "let any Potentate buy it, and next day 'tis worth a million of pounds sterling." All negotiations, however, proving idle, Pitt comes home himself. Meantime, both in India and in England, stories about the great stone had been in circulation. "It had been snatched out of the eye-socket of Jauggernaut," though how a rough stone would have any value as a brilliant it is hard to see. The man who stole it concealed it in a gash in his leg, and—so ran the coffee-house tattle—was murdered by an English captain for the sake of the plunder. In time, the tale came to be that Pitt was the robber, and, to this day, this story is embalmed in more than one popular history of the celebrated diamonds of the world. Pope seemed to have got hold of one of these libels, and gave currency to it in the history of "Sir Balaam." "Asleep and naked as an Indian lay, An honest factor stole a gem away: He pledged it to the Knight, the Knight had wit, So kept the diamond, and the rogue was hit." That the Poet had Pitt in his mind when he penned these lines is proved by Mr. Courthorpe's discovery that the first version ran, "So robbed the robber, and was rich as P—," "The Knight" was probably Sir Stephen Evance. It is questionable whether the subject of all these tales knew much about them until he arrived in Europe, when he made a solemn declaration in writing at Bergen, in Norway, affirming on oath the utter falsity of the calumnies. Why he was in Norway at all has never been clear, and this circumstance has hitherto thrown doubt on the *bona fides* of the documents. But Colonel Yule shows that he had been carried there by taking passage at the Cape on board a Danish vessel, which landed him at Bergen.

The real facts, as now revealed, show that two or three years after his arrival in Madras Pitt first heard of the diamond, and, in 1701, was approached by Jaurehund, a great dealer, with the object of inducing him to buy it for two hundred thousand pagodas—a pagoda varying in value from six to nine shillings sterling. But the Governor refused more than thirty thousand. Finally, after a long haggling, which affords a vivid picture of Oriental chicanery, it was acquired for forty-eight thousand pagodas, and certain people then living are mentioned as witnesses to the transaction. There is thus no ground for the long-lingering libel, or for the supposition that Pitt, rough blustering character, and greedy of money though he was, without much delicacy when gain was concerned, did not come honestly by his gem, though where Jaurehund obtained it is still a mystery. It is even doubtful considering the high rate of profit ready money brought in India, the

commissions and other payments he had to make, and the long time which elapsed before he realised on his venture, whether Pitt was very much in pocket. It is certain that the possession of the stone yielded him nothing but unhappiness. Nobody was permitted to see it, and when he set out for France, to carry it to the Regent's Agent, a jocular hint of the landlord of the inn in which he passed the night at Canterbury, that he had a "pebble" with him, threw the Nabob in such a violent rage that he was not appeased until he obtained a guard of soldiers to Dover, and had even persuaded two of the officers to accompany him to Calais, where the Royal jeweller met him to inspect the gem. The Regent, it would seem, by John Law's advice, bought the diamond for two million livres—the value of the livre being at that date one shilling and fourpence sterling—depositing forty thousand pounds of the one hundred and thirty thousand pounds in England before Pitt left with it. But the balance was never paid, though three boxes of jewels were handed over as security. When the debt was claimed from the French Government, it was fully admitted, but the Ministry declared it impossible to enter into the past transactions of the Regent. Accordingly, the sum really received by Pitt must have depended on the value of the jewels pledged as security, though of this part of the business we know nothing. The after-history of the Regent Diamond is, however, tolerably familiar. It formed one of the French Crown jewels. At the Revolution it was stolen, but recovered, and duly pawned with Vanderberg, the Amsterdam banker, for money to buy "horse furniture for the Army of Italy." The banker, M. Bapst tells us, exhibited it in an ordinary glass case. On some friend suggesting to him that this was a rather risky proceeding, the Dutchman answered, with a twinkle of his eye, "The Regent that is in the glass case is a worthless sham; the real Regent is in my wife's stays." Napoleon mounted the diamond in the pommel of his State sword. At the *débâcle* in 1814 Marie Louise carried it off to Blois; but it was restored by her father, and, after figuring in many pageants, lies at this moment in the Treasury cellars in Paris, waiting until it can be transferred to a safe receptacle, where, with the Dey of Algiers's watch, the Dragon Ruby, and other precious objects reserved from the sale of the Crown jewels in 1886, it can be exhibited to the public.—London *Standard*.

NOTES ON THE DRUG MARKET.

(From Messrs. Gehe, & Co.'s Half-yearly Circular.)

CINCHONA.—As regards druggists' barks Maracaibo and Porto Cabello barks have throughout been in good demand at comparatively far too elevated prices; these very poor barks are still frequently bought in some parts of the Levant and in Russia from old habit. *Succirubra* has of course been very cheaply obtainable from Java. The grey Guayaquil, Loxa, and Huanoco barks have continually been scarce and dear; genuine Loxa bark especially is very seldom met with. Red bark was inquired for from Holland and Italy, but the selection is a most unsatisfactory one, and it seems that the trees which yield this bark are in the expiring stage.

OTTO OF ROSE.—The production of otto of rose in the Balkan mountains, in the neighbourhood of Kezanlik, yielded about 500,000 meticals last year, *i.e.*, about the same quantity as in 1887. Nevertheless, the price was quoted a little lower than in the latter year, and almost equalled that of the cheapest seasons on record; partly because good supplies were still left in stock from 1887, partly because increasing attention is now being

paid to the manufacture of otto of rose in other districts. And although the quantities which are gained in Northern Bulgaria, in the neighbourhood of Broussa, as well as in the Caucasus, cannot as yet compete with a production of 2,400 kilos., such as we may calculate to be obtained in Roumelia, still they are sufficient to compel some caution in the pretensions of the Roumelians. [The Broussa plantations are not, as far as we are aware, situated in Northern Bulgaria, but near Broussa, on the Asian side of the Bosphorus.—Ed. O. & D.]

VANILLA.—According to all reports a complete failure of the vanilla crop has succeeded last year's abundant yield. In Mexico the crop has been entirely destroyed by rain, and the news of this fact caused prices to advance a dollar per lb. in one single day on the New York market. It is true that Mexican vanilla has ceased to play a part on the European markets for many years, but the varieties here current, such as Mauritius, Réunion, and Seyohelles, have also shown a considerable deficiency. The 1888 crop in Mauritius is estimated at only 34,000 lb., against three times that quantity in 1887, and in Réunion at 11,650 kilos against 41,000 kilos, while in the Seyohelles, the bulk of the crop having been shipped already, not over 5,000 lb. are said to remain in the hands of the growers. The aggregate of these figures is not at all sufficient for the annual consumption, which hitherto required from the London market alone 400 tins, or, say 5,000 lb per month. The stocks also have been lightened considerably. In the middle of January, 1889, the first and second hands together in Paris and Bordeaux owned only about 22,000 kilos, while in London there were 300 tins, against 1,500 tins in 1888, and 400 tins in 1887. The London quotation for medium lengths was: 1889 = 12s 6d, 1888 = 16s, 1887 = 21s per lb. Under the above-pictured circumstances speculators have seized upon the article. The advancing tendency which has become strongly marked since January has developed itself further and will continue to progress, and low prices must not be expected again this year. It is reported that the prospects for the 1889 crop also leave much to be desired. The quality of the 1888 has been a very good one, the long beans which were so scarce last year are very well represented this season, and even beans 9 to 10 inches in length are frequent. But there is a noticeable lack of short beans from $4\frac{1}{2}$ to $5\frac{1}{2}$ inches long, and for this variety prices are paid which are, perhaps, out of proportion to the others.—*Chemist and Druggist.*

BENGAL PATENT STONE.

The experiment narrated in the following extract from the *Indian Engineer*, seems to have been more successful than was an attempt made in Ceylon in Major Skinner's time to manufacture artificial stone, a gentleman connected with an English Firm being got out for the purpose. The local experiments were conducted at the Government Factory and the publication of details would be interesting. We quote as follows:—

From time to time various materials have been combined with cement with the object of making a solid mass or concrete for building and engineering purposes, the most important point in this amalgamation being to use, with cement, such materials as do not possess a regular surface, and are also slightly honey-combed and very hard. They have all however, been found defective in one or other of these essentials, as, either, owing to the nature of the material used, they have scaled like ordinary stone, or, owing to its not being porous, there has been nothing for the cement to key; and the whole after very little wear has crumbled away like sand and become perfectly useless.

The main feature of the Patent Stone, introduced by Messrs. Garlic Bros., of Calcutta, is that the chief ingredient used is harder than flint, and in shape most irregular, and in addition, slightly honey-combed, so that the cement finds opportunities for grasping and keying the aggregate, and forming one solid and almost indestructible mass.

The want of a moderately-priced, and thoroughly durable, stone is greatly felt in India, more especially in lower Bengal, where stone is almost non-existent; and the Patent Stone, will be found valuable for many purposes. It is being extensively used by the Bengal Public Works Department, the Calcutta Municipality, the Military Authorities, and the Calcutta Tramways Co.—for stable-floors, surface-drains, boundary posts, etc.—and by private firms, and others.

Street's foot-paths, floors, godowns, mills and houses are all paved in the same manner. The surface is perfectly smooth and even, and there are no joints. Floors are perfectly damp-proof, fire-proof, and vermin-proof; almost indestructible, clean and even; they are said to wear better than stone, and require no repairs, as in the case of asphalt or cement; and be unaffected by the greatest heat.

THE DUTCH MARKET.

AMSTERDAM, April 24th.

CINCHONA BARK.—The sales in Amsterdam on May 2nd will consist of 2,244 bales and 95 cases, about 1,865 tons, viz.:—Java Bark from Government plantations, 410 bales and 31 cases, about 35 tons; private 1834 bales and 64 cases, about 148 tons. East Indian bark 37 bales, about 3 tons 5 cwt. This quantity is made up as follows: Druggists' Bark: Succirudra quills 62 cases; broken quills and chips 348 bales 24 cases; root 57 bales 2 cases; C. Schukraft quills 7 cases; broken quills and chips 41 bales; root 6 bales; Lancifolia broken and chips 6 bales; root 2 bales; Manufacturers' Bark (about 147½ tons): C. Officialis broken quills and chips 35 bales; C. Ledgeriana broken quills and chips 1,402 bales; root 261 bales; Hybrid broken quills and chips 67 bales; root 19 bales. Manufacturers' barks contain about 6 tons of sulphate of quinine or 4½ per cent on the average. About 11½ tons contain 1-2 per cent of sulphate of quinine; 35½ tons 2-3 per cent; 47½ tons 3-4 per cent; 15½ tons 4-5 per cent; 7 tons 5-6 per cent; 21 tons 6-7 per cent; 3½ tons 7-8 per cent; 6 tons 8-9 per cent.—*Chemist and Druggist.*

ALL ABOUT TEA PROSPECTS: NOTES ON PRODUCE AND FINANCE.

The Chinese tea merchants, especially those at Kinkiang, are quite elated at the success of Chinese teas last season, and they already think that a reaction in their favour has set in. Contracts for the ensuing season to the amount of from 700,000 to 800,000 taels have already been settled with the up-country growers. It is quite clear that the supply of tea is not likely to diminish, and that prices will not be in the ascendant. It will be a keen competitive struggle in which the fittest gardens will survive. But new markets must be opened. It is an imperative necessity. The Ceylon planters have recognised this from the first, and have been more active than Indian planters in practical work in this direction. There is the European Continent to be won, and no time should be lost before organising.

That which enterprise in combination has pondered long over and recently undertaken—viz., the opening up of new markets for Indian and Ceylon tea—has been taken in hand very vigorously by Mr. S. Davidson, of Belfast. Not content with opening the campaign in the United States, Mr. Davidson, with his usual pluck and persuaunce, is, we hear, laying siege to Continental markets, and his famous Sirocco teas will be heard of in France and other countries before long.

The *Statist*, referring to the position of tea and the fall in prices, says:—“While in the Mincing Lane markets there has lately been a good deal of speculative activity in some directions, notably in sugar, there is one department which has been extremely depressed. Where the tea trade, as in past years, dependent on the statistical position of China tea alone, we should probably have had prices going up by leaps and bounds; but, as we have on morean it

one occasion of late pointed out, China no longer rules the roost. Between 1879 and 1885 the consumption of China tea gradually declined, and in the last four years it has rapidly fallen off. Our home consumption from about 10,600,000 lb per month in 1879 has dropped to 6,600,000 lb per month in 1888. In the same period tea of British growth—that is, Indian and Ceylon—has risen from about 2,800,000 lb per month, as an average of the year 1879, to 8,800,000 lb. in 1888. China brokers now complain that they are in the ranks of the unemployed. The contrast of monthly consumption is remarkable, and is shown below:—China Tea.—1888, 6,600,000 lb.; 1879, 10,600,000 lb.; decrease, 4,000,000 lb. India and Ceylon Tea.—1888, 8,800,000 lb.; 1879, 2,800,000 lb.; increase, 6,000,000 lb. As an indication of the depressing character of trade in China tea, we may say that the same quality of China teas which, on arrival of the first shipments of current season's teas was sold at 1s 3d per lb., has quite recently been offered in the market at as low as 9d per lb. There was a hopeful feeling in the market at the time the new season's tea began to arrive, but it has been found that the tea has been of an inferior quality. Being badly cured, it has, consequently, not kept well. The Indian and Ceylon teas of the past season have also been somewhat inferior as to quality, and the only crop which has been both sound and good as to quality has been the Java growth. Undoubtedly the consumer has been secured from a high level of prices, consequent on the shrinkage in the import of China teas, by the great development in the Indian and Ceylon descriptions. Thus, in the season of 1885-6 the actual deliveries of Indian tea amounted to 60½ million lb. and for the current season, which ends on May 31st, based on known results of ten months and estimates of the remaining two months, a delivery of over 90½ million lb., is expected. This is approximately an increase of about 50 per cent. in the consumption compared with four years ago; but the comparison sinks into insignificance with the proportionate increase when we refer to the statistics of Ceylon tea. In the period from June 1st, 1885, to May 31st, 1886, about 3,930,000 lb. of Ceylon passed into consumption in this country. In the season which ends on May 31st 1889, with the known results of ten months and estimates of April and May, there appears to be every probability of deliveries to the aggregate amount of 23,350,000 lb, an increase of about 500 per cent. Undoubtedly one great cause of the expansion of consumption which has been going on year by year has been the decline in prices. As the industry develops, the greater area planted admits of more economical working, and the use of mechanical appliances admits of more economical production. Probably in part the decline which has lately taken place has been due to the comparatively poor quality as well as to the continuance of savings found practicable in cost of production. Be that as it may, the fact remains that the last week or two teas have been sold at unprecedentedly low prices. For example, the same quality of Indian tea which late in 1881 was sold at 1s 2½d per pound has changed hands quite lately at 7¼d per pound, which is exactly 50 per cent fall.

"The increase in production of India and Ceylon is likely to still further continue, as the exports of Ceylon tea for the new season are expected to be more than 50 per cent. greater than in the previous season; and the India crop available in the United Kingdom is estimated as likely to be 94,000,000 lb. as against 86,000,000 lb, available for exportation to the United Kingdom.

"We come to the fact that if production of tea continues to increase as it has done the last three or four years, new markets must be sought. Some time ago India endeavoured to develop a new market in the United States, but shippers went about their work in a very ill-considered manner; they flooded a market where Indian tea was scarcely known with such large quantities that it was impossible to dispose of the arrivals; indeed, the teas so rushed into a new channel not prepared to use them had to be offered by forced sale, and actually a large quantity of what was sent from India to

America came to the United Kingdom for consumption. With such experience, it is only natural to expect that any development of a new market will be well considered before it is undertaken. There is no reason whatever why the United States and Canada, as well as Europe, should not be open to consumption of Indian and Ceylon qualities. Of course, the United Kingdom stands far and away at the head of tea-consuming countries, followed by the United States and Russia. Considering the population, a very large quantity is taken by the Australasian Colonies, and an appreciable amount by Canada. The consumption per head is largest in the Australasian Colonies and New Zealand, the latter taking the lead with 7·67 lb. per head followed by the Australian Colonies with 7·67 lb. per head. India is developing trade with Australasia, but still the bulk of the tea consumed even by those Colonies is derived from China. So far as the United Kingdom is concerned, the expansion of consumption of British-grown tea in the Australian Colonies will give us no direct benefit, as shipments will be made direct from India and Ceylon; still it will give us an indirect benefit in the employ of shipping, increasing the spending power of the planters who buy from the mother country, and giving dividends on English capital employed in the cultivation of tea in British possessions. In the United States we may expect a development of consumption of India and Ceylon growths provided the planters suit the tastes of the market. In case the United States consumers 'take to' such teas, the United Kingdom will secure a more direct benefit, as the tea will pass through this country, though probably to some extent it will be shipped to San Francisco, and will be conveyed overland to the eastern parts of the United States. The most direct benefit will be secured from development of tea drinking on the Continent, and by the Continent we mean Western Europe, as it will undoubtedly be a difficult task to oust China teas out of the Russian market.

"The consumption in Western Europe, however, is not large, but the two countries which ought to be exploited for an increase in trade with British possessions growing tea are Holland and Germany. The former, according to Messrs. Gow, Wilson, and Stanton's recently-published statistics, consume only about 1¼ lb per head of population per annum, while the tea drunk in Germany is rather less than 1 lb per head. France and Belgium stand virtually nowhere in consumption, taking only 0·03 lb per head, and Spain rejoices in the very small fraction of 0·02 lb per head. A good deal ought to be done at the Paris Exhibition in introducing British-grown tea to the notice of our Continental neighbours, though it has to be borne in mind that in France the duty on tea is really prohibitive, except for the wealthy; nothing that is worth drinking can be obtained under about 5s per lb, or two to three times as dear as the retail price in London."

Mr. Picton, the member for Leicester, is the champion in the House of Commons for the abolition of the duty on tea. He won't be happy till he gets it abolished, although there is not the slightest chance of his being happy just yet. It is as well to know that Mr. Picton intends to peg away at the subject, and that he regards a tax on tea, which is, in his opinion, a necessity of existence, as unjust and iniquitous.

Those who maintain that the trade in bogus tea no longer exists will take some interest in the following. The police of Dunkirk, acting on information from the Municipal Laboratory, arrested on Saturday two grocers of that town on the charge of having for several months sold large quantities of dyed leaves under the name of tea. Both the tradesmen were able to show that they had been supplied by a wholesale firm in Paris. Samples were accordingly bought from the firm, by order of the Parquet, and were sent to M. Riche, a chemist. His report shows that the leaves submitted to him are not tea-leaves. They are—like most dried leaves—of a brownish colour; but this is hidden under a thin coating of a bluish-green substance, which easily rubs off. Their appearance was exactly that of gunpowder tea. Unlike the celebrated nutmegs, it has

been impossible to tell to what plant they belong, the leaves having been punched out of larger ones. The wholesale merchant denied any knowledge of the fraud, and stated that the bogus tea had been sold by an importer, whose name he gave. The latter says that he received it directly from an English firm of Canton.—*H. & C. Mail.*

COST OF PRODUCTION OF TEA IN CEYLON.

A tabular statement issued by a local contemporary affords estimates of the cost of tea on an estate of 250 acres in full bearing having good factory, adequate machinery and fuel on the estate, at various rates of yield. The results arrived at are 50 cents per lb. f. o. b. Colombo at a yield of 150 lb. per acre; 46 cents at a yield of 200 lb. per acre; 40 cents at 250 lb.; 37 cents at 300 lb.; 35 cents at 350 lb.; 32½ cents at 400 lb.; 31½ cents at 450 lb.; and 29½ cents at 500 lb. per acre.—On a larger estate, say of 400 acres, the cost might be reduced 1 to 2 cents per lb.—The average yield for Ceylon may, we suppose, be taken at 300 to 350 lb., so that 35 to 37 cents or the equivalent of 6d per lb. may be taken as the average cost of Ceylon tea f. o. b. Colombo. We have received from an experienced planter a letter and tables—to appear in our next issue—which go to show that at 8d per lb. average it will require 500 lb. per acre to give a profit of R50 per acre; 400 lb. sufficing if the average, as at present, be not below 9d.—An average of 6½d at 500 lb. per acre will merely cover the expenditure.

THE COCONUT PALM.—The following paragraph appears in the "Kew Bulletin" for January:—

Cocos nucifera. Coconut. At an elevation of 3,000 feet and 200 miles from the sea the coconut palm is scarcely worth cultivating. It is, however, here and there in several varieties. [In other parts of Mysore, especially when water is near the surface, the cultivation of the coconut is said to be fairly profitable. The export of fresh coconuts from Mysore State in 1880—81 was valued at 10,452, and of coconut oil at 666l. *Imp. Gaz. of India*, vol. x. p. 102.]

In Ceylon, there are flourishing coconut tops or groves near Matale, Gampola and Badulla from 1,400 to 2,200 feet above sea level: in the Matale Valley there are quite large fields bearing very well, we believe, and about 100 miles in a direct line from the sea. Solitary coconut palms are grown at 3,500 feet altitude in Ceylon, but they do not bear fruit. And yet in the Western Province planters 40 to 50 miles from the coast are supposed to have gone too far inland. The proper coconut belt, we suppose, would not be reckoned at over 10 to 15 miles from the shore.

RICE GROWING IN BRITISH GUIANA.—Mr. Hon. W. Russell is the subject of a long and interesting paper in the local quarterly *Timehri* which we are reprinting in the *Tropical Agriculturist*. Mr. Russell shows that if a proper use were made of the well-watered rich waste land in this British South American colony, there would be no need to import any rice at all. One estimate he gives shows a profit of 12 dollars an acre in 6 months, another under more favourable circumstances shows 53 dollars profit per annum. Instead of two crops a year, the Guiana fields can give three crops in the year, or five if ratoon crops are also counted. This paper is followed by one by Mr. Gilzean giving interesting details of practical experiments in rice-growing made by him with his labourers. He shows a profit of 21 dollars an acre in three months.

COTTON CULTIVATION.—The place to cultivate cotton successfully on a big scale would seem to be on the wide expanse of fine soil—some 10,000 to 15,000 acres to choose from—available under the Wallaway irrigation works. We believe that Mr. Ward speaks in high terms of the fitness of the soil both for cotton and tobacco; but in respect of the latter product we understand that a visit to the spot by two of the Directors of the local Tobacco Company resulted in their rejection of the site—perhaps, for the reason that it was exposed to the North-East monsoon winds so much dreaded in connection with tobacco curing. This would not apply however in reference to cotton.

COCONUT CULTURE AND ITS ENEMIES.—*On dit*, that the Government Agent, Western Province, is to call a Conference of the Mudaliyars and other leading headmen of his province, together with some of the oldest representative planters, to see if there is anything in the persistent rumours of leaf-disease in coconuts. Specimens will be produced and the headmen can compare notes while the oldest planter will be able to say how many years back it is since he saw the pest in question. It would be well to have specimens of the beetle enemies of the palm, in case of a new one turning up. Mr. Saunders cannot but recognise the duty devolving upon him in reference to what is the most important agricultural industry of his now contracted sea-borde Province.

GOVERNMENT TEA FACTORY AT PERAK.—In the *Perak Government Gazette*, for April 19th we notice the following advertisement:—

Tea.—One thousand pounds of tea for sale. Manufactured at the Government tea factory, Perak. Prices: Quality, Unassorted, 65 cents (Mexican dollar,) or 3s sterling, per lb. delivered in Europe, Colonies or America. Quality, pekoe souchong, 60 cents (Mexican dollar,) or 2s 9d sterling, per lb. delivered in Europe, Colonies, or America. Higher qualities of tea as well as tea of lower grades obtainable. Tea packed in lead, in one or two pound packets. A reduction in price on orders exceeding 20 pounds. Orders booked and further particulars supplied by the superintendent, Government plantations, Perak, Straits Settlements. The Hermitage, August 20th 1888.

At present there is very little tea in Perak, but the Government appear to be determined to encourage its cultivation.

THE TEA ASSOCIATION, we (*Pioneer*) are glad to see, is awakening to the rapid development of the Ceylon trade. The exports from that island have made phenomenal leaps within the last few years, and the total outturn next year is estimated at 45 million pounds, or close on half that of all the Indian gardens in 1888, though the latter have a start of over thirty years. At the same time the exports from India this year have risen by from ten to thirteen million pounds. So extraordinary an advance in production must very quickly outrun the increase in demand due merely to the growth of population in the United Kingdom, and a fall in prices, with a shrinkage in the profits of the planters, must result unless the cost of production is reduced and new markets are found. In this latter regard the Assam planters have heretofore been somewhat apathetic: but the remarks of Mr. Stuart on Friday justify the hope that in the future they will exhibit more of that enterprise and push for which their Ceylon brethren are so honourably distinguished. To drive foreign teas from India and establish Indian teas in the comparatively virgin ground of Russia, Australia and the United States, these are objects which, in these days of keen competition, must needs occupy a first place in the attention of the Tea Association, if the traditional prosperity of the Assam gardens is to be maintained.

NOTES ON CINCHONA.

BY ANTON KESSLER.

(Translated for the "Tropical Agriculturist" from a reprint of the *Journal of Industry and Agriculture at Batavia* of September 1886, by J. Dent Young.)

(Continued from page 147, September 1885.)

As is well-known, a callus forms over the edge of the cut where it intersects the layer of cambium, out of this callus roots subsequently spring. In the case of woody cuttings, a considerable time has to elapse before the heart of the sectional surface becomes thoroughly covered with well-formed bark, during which interval of time that part of the cutting is particularly liable to decay. I do not consider that it is advisable to plant cuttings on land where much canker has appeared. If the cuttings are the upper parts of very young grassy seedlings which have thrown out roots, then perhaps the case is different.

These upper parts of the seedlings consist still entirely of strong vigorous celluloses, the woody celluloses not having yet appeared, the growth therefore is more rapid and keeps pace with the general development of the plant.

Still, however, seedlings are most to be recommended, as the least vulnerable in lands predisposed to canker.

In hollows and on very steep land, situated under steep and long hillsides, the escape of the water is frequently very defective, which is destructive to cinchona planting. In such places the canker is always the most inveterate. Thorough draining is generally successful, and trees in the first stage of the disease recover after the soil has been well dried.

Occasionally the canker is found on slopes of hills so steep, that we might well assume there could be nothing to fear from want of sufficient escape for the water, but estates are named, which though situated on very steep ground, nevertheless are more afflicted with canker than others.

On plantations where the plants have not been put too deeply into the ground, the evil is probably caused by the shallowness of the soil, with an impenetrable substratum of rock or earth, or by radically bad cultivation. In the former case there is little to be done; similar circumstances are in all probability the reason of the less success of Ceylon in the cultivation of cinchona.

In a new undertaking, the utmost attention is to be paid to the selection of a suitable site; if this is not available, little good can be hoped for from the enterprise.

At the same time the results of an injudicious system of cultivation must not be attributed to the quality of the soil. For the regular progress of the necessary chemical processes in the soil (I allude particularly to the nitrification) an easy admission of oxygen into the ground is indispensable. If this be excluded by insufficient tillage, a diminished luxuriance of growth in the plant is the penalty for the neglect. In consequence of the predisposition of the cinchona plant to decay, the growth of weeds under the trees forms another source of danger, by obstructing the evaporation of dew and rain, so that the collar of the root, even above the ground, is kept in an unhealthy state of moisture, which as has been already mentioned tends greatly to superinduce canker.

Still we frequently hear planters defend the assertion that clean weeding of cinchona plantations is not of much importance, and though we often see plantations with a growth of tall weeds on them, which are seldom cleared away, and when weeding is done, it is only by hacking down the

weeds level with the ground. The temptation is great where capital is limited, to endeavour to keep down outlay by resorting to such unsatisfactory upkeep. But in the end the results will not be found to justify such a system, as the saving effected thereby will have to be repaid at an usurious rate, in reduced production, when the harvest comes to be gathered.

There are kinds of manure which by their hygroscopic effect keep the soil constantly clammy and damp, such as Chile saltpetre (nitrate of soda) for instance. However usefully this fertilizer may therefore operate in some kinds of cultivation, I consider it unsuitable for cinchona, particularly in very wet districts, and should such experiments as these above described by me tend to show that fertilizers containing hydrogen and inorganic matter improve the growth and the proportion of alkaloids of the cinchona plant, then will the cultivator seek for help not from saltpetre but rather from sulphate of ammonia.

Happily canker only appears here and there in the cinchona plantations of Java, and does not come in the form of a real pest, as appears to be the case in Ceylon, here it is only "one of the thousand natural shocks which vegetation is heir to." Nevertheless the disease is well worthy of public consideration. The fact of its being sporadic, calls for the most strenuous efforts to combat it, and therefore a knowledge of its nature and origin is of the highest importance. The tendency to decay under the slightest provocation, which is found in the nature of cinchona deserves to be kept in mind in extending its growth by artificial means. Whilst in planting cuttings of tea or other woody growths, incisions are made at the ends of such cuttings as are placed under ground, for the purpose of hastening the sprouting of roots, such a proceeding is not to be recommended in the case of cinchona. These incisions generally cause decay, and under the most favorable circumstances they are perfectly useless. It is sufficient to give the twig or cutting a very sharp curve under ground and to peg it fast, so that it shall not be wounded in any part. The contraction of the flow of sap by the compression of the tissues and cells in the bend is sufficient to cause it to throw out roots. After a shorter or longer time, which varies from 3 to 14 months roots will be formed of sufficient strength to make the shoot or cutting self-supporting, and it can be severed from the mother tree and either transplanted, or it can be allowed to remain another month in the spot where it has struck root, before transplanting it to where it is intended to grow.

Very young grassy suckers frequently strike root satisfactorily in three months. Other branches sometimes take over fourteen months before they become sufficiently rooted.

In transplanting layers after separation from the parent tree, it is of great importance that they should be well pruned, by which term I mean that all side branches should be removed, and at the same time each leaf should be reduced to one-third of its size, for the purpose of diminishing the evaporation. This evaporation is not to be lightly regarded. To ascertain its influence on cinchona, I adopted the following means:—I planted a *Ledgeriana* seedling which had three pairs of leaves in a glass vessel. With a piece of flat glass having a hole bored in the middle, and cut in two through the centre hole, I covered the vessel in such a way as to allow the stem of the plant to go through the hole in the glass plate, whilst a second hole allowed the earth in the vessel to be sprinkled from time to time with distilled water. The joints between the rim of the glass

vessel and the plate of glass, the two halves of latter and round the stem were made air tight by means of melted wax, whilst the perforation made to admit of watering, was hermetically closed by means of a separate piece of glass coated with grease. The whole was then weighed, and the weighing was repeated from time to time, whilst weighed quantities of distilled water were employed as required to moisten the earth through the opening provided for that purpose.

The loss in weight of the plant must of necessity be the consequence of evaporation, and must thus indicate the quantity by weight of the water carried off by evaporation.*

The plant continued fresh, and in the shade out of rain and wind, lost in 52 days 172,545 grams of water. In the sun the loss of weight was nearly doubled.

The weight of the plant itself dried in the air was 3,850 grams (after drying in a temperature of 100° to its fixed weight, it was only 1,430 grams), so that in the course of 52 days it gave out in evaporation 44.81 times its own weight.

The calculation is as follows:—

Loss of weight in grams	172,545	=	44 81
			times its

Its own weight	3,850	times its
		own weight.

Every tree in healthy condition forms as many leaves as are necessary, so that these proportions may be assumed to hold good, practically for larger or smaller plants. As layers have not only their own roots to supply them with sap, but those of the parent tree as well, so long as they hold their existence in common with the parent tree, they form a mass of leaves proportionate to the plentiful supply of sap with which they are fed. After separation it consequently becomes necessary to remove the greater part of the leaves from the layer, as the roots it has formed cannot be sufficient to supply sufficient moisture from the soil to make up for the quantity evaporated by a large expansion of leaves, and withering and decay would be the consequences. Since such is the case when the layer is only severed from the parent tree, the danger is much increased, when, besides, being severed from the parent tree, it has to be transplanted, the power of the roots being still more reduced.

What has above been said regarding suckers holds good quite as much with reference to layers. The trees generally grow with less vigor than seedlings and grafts, and the latter are greatly to be preferred. If we had seed at our command of such a high order as to leave no room to fear degeneration, then no planter would think of preferring trees artificially propagated. So long however as such seed is not to be had, the artificial propagation is the most certain means of improving the plantations. Grafts stand in the first order; after them come cuttings and layers. Analysis by the Government chemists has fully proved that the proportion of cinchonidine in the bark is somewhat increased by grafting on *Succirubra* stems; there is, however, a simple means for avoiding the unfavourable influence of the *Succirubra*, namely, by grafting on *Ledgerianas*.

Ledgeriana seed of plantations yielding 6 or 7 per cent of quinine without much cinchonidine is easily obtained, whilst the raising of *Ledgeriana* from seed is not more expensive than it is from

* In consequence of the small development of the plant, it was not necessary to take into consideration the increase of weight caused by the absorption of carbon from the atmosphere.

cinchona seed. Since general opinion has decided that *Ledgeriana* seedlings grow as fast as *Ledgeriana* grafts on *Succirubra* stems, there can be no fear of a less robust development of a graft plantation on *Ledgeriana* stems, as compared with another in which *Ledgeriana* is grafted on *Succirubra* stems; whilst on the eventual entire uprooting there is an advantage which is by no means to be despised, to be derived from the greater value of root bark of *Ledgeriana* compared to that of *Succirubra*. Repeated experiments with trees of three, four or five years old on plantations under my management prove that the bark of the root, the collar of the root and the portion of the stem below the graft of *Ledgeriana* seedlings constituted about five-twelfthths of the bark produced by the entire tree, so that when the whole harvest amounted to 1,200 grams, 500 grams may be reckoned as derived from the portion of the tree below the graft. In harvesting by uprooting it makes a considerable difference, whether the bark yields 1½ per cent or 6 per cent.*

It is well to attend to these and similar matters, for although it may not be every planter's intention to harvest by uprooting his grafted trees, yet in the end uprooting has to be carried out on every *cinchona* plantation, and it must always be a great advantage to obtain root bark of superior proportions of quinine, an advantage which is eventually unfailing, although it may be deferred.

Tjikoraia, 27th June 1886.

A CEYLON PLANTER'S VISIT TO THE NILGIRIS.

Mr. Thos. Farr of Bogawantalawa returned yesterday via Tuticorin from what was evidently a very pleasant visit to the Nilgiris and the Wynaad, where he has seen much that was new and interesting to him.

Mr. Farr seems to have been very much impressed with the magnificent fields of *cinchona* to be seen growing vigorously in the Nilgiris, and the still vigorous coffee which is to be met with in South-East Wynaad. To a Ceylon planter whose experiences of *cinchona*, though extensive, are not usually very favorable, it is certainly enviable to hear of the large sheets of *Officinalis* which Mr. Farr saw in and around Neddivattum, the Government *cinchona* garden. Staying on an estate situated alongside this Government garden, Mr. Farr was able to look over an expanse of upwards of six hundred acres of *Officinalis* seven years old, in which there literally was not a vacancy—a dark even sheet in which canker was absolutely unknown, and in which the trees were really magnificent. Instead of finding everyone ready to throw a stone at *cinchona* cultivation and to regard it as useless labor, the planters in the Nilgiris appear quite content to wait until Ceylon shipments of bark shall have fallen to smaller limits, as the bark from their own trees is generally of high analysis, and, even at present prices, such loppings as are from time to time necessary, are amply sufficient for current expenditure.

Neddivattum and the gardens which surround it are at an altitude of over 6,000 feet, and few *succirubras* are cultivated; but that which astonished the Ceylon planter more than anything else was the evenness of the fields of *cinchona*, for, although the actual growth at the same age was generally not much, if any, better than what we are accustomed

* This proportion is what holds good, as I have already said on plantations under my management where the soil is loose and soft. In stiff loam and clayey soil it will be more to the disadvantage of the rootbark. Most of the *cinchona* enterprises in West Java have however loose soil, and every planter can satisfy himself by experiments of the relative proportions that may rule on his own plantation, which will show him the importance of the above remarks. The weight of the bark below the graft is always considerable.

to in Ceylon, still, clearings of large expanse exhibit the same healthiness and vigor that are seen in Ceylon in patches only, and in trees in selected and sheltered spots amongst the coffee.

In reply to our inquiry, Mr. Farr said that canker is absolutely unknown in the Nilgiris, and, in all his journeys through many estates, he never saw such a thing, or even that flag of distress so often hung out by cinchona trees in Ceylon—a red leaf. The Nilgiri planters do not seem to have much fear of Java, but are still timorous of the enormous quantities which they fear may yet be shipped from Ceylon. They await with confidence the time when those shipments shall have dwindled to small proportions, and the price of the article have again risen in the markets of the world. One reason why they have apparently despatched such comparatively small quantities of bark for shipment of late years has been a fact which certainly has not operated with us—they have only sent bark shavings because they were not compelled to send any other. Much, if not the major portion, of the bark sent from Ceylon recently has been taken from dead or dying trees, whereas trees decay or die on the Nilgiris at all events, only after they have reached their full maturity. The chief enemies of cinchona in that part of the world appear to be frost and sambur, the ravages of the latter, particularly on young clearings, being extensive.

With regard to coffee, Mr. Farr saw quite sufficient to convince him that the old King was far from dead either in the Coorg district or in the Wynaad, and, although he did not actually visit the Ouchterlony Valley, he describes it, from a view obtained of it from a distance, as a dark and even sheet of coffee, as healthy and apparently as vigorous as any Ceylon could show in its best days. Leaf disease was prevalent everywhere, but coffee planters there did not seem to regard it as so very destructive as we have known it to be in Ceylon, and, except on estates without shade in the South-East Wynaad, it does not as yet appear to have had any very destructive influence over the coffee. The difference of its effect on coffee without shade and coffee under shade was most marked, particularly in the last-named district, where all the shaded coffee was extremely healthy and in good heart, and Mr. Farr describes one of the estates which he visited in that part of the world having a very large blossom just in spike as being "a sight good for sore-eyes." Many estates are still giving handsome crops of three, four, and in some cases five, hundredweights an acre, which at present prices at home and present exchange, must yield most handsome returns.

We hope, however, that Mr. Farr will give us his experience in his own words, and feel sure that they will be extremely interesting to all planters in Ceylon who, although now more largely dependent upon tea than upon their old staples, have yet not lost all interest in, or dependence upon, coffee.—Ceylon "Times."

COFFEE AND CINCHONA IN THE NILGIRIS AND WYNAAD.

Upon approaching Coonoor, the existence of our old familiar friend Coffee became apparent. Down the slopes of the valley under the grand old "Droog" dark green fields of well-tended coffee reached from precipice to river. Old trees with rugged stems such as I have seldom seen in Ceylon, were living and vigorous proofs of an exceptionally rich soil, and although our old enemy *Hemileia Vastatrix* was not hard to find, I could not help feeling that here at least she could not claim to be *Victrix* as yet.

Crop operations on these Coonoor estates were almost over, and the hearts of the planters were gladdened by the sight of an abundant and healthy "spike," which showed itself ready to develop with the first showers of March. I am not prepared to say that leaf-disease has not affected the coffee estates of Coonoor. Certain fields there are and ridges where the soil is poor, upon which the fungus has

left its mark; but these covered a comparatively small area and will probably soon be covered with tea and cinchona. That strong and vigorous coffee still exists both on the Nilgiris, in the Ouchterlony Valley and in the South East Wynaad cannot admit of a doubt. Crops are naturally, the best—in fact the only—test as to its value; and from what I gathered from the planters, whose acquaintance I was fortunate enough to make, so far there is little ground for complaint. In Coonoor I visited fields of coffee some 30 years old, and was equally impressed with the vigor of the trees, the promise of blossom, and the richness and depth of soil. Cultivation is attended to and manure is liberally distributed over deserving fields. The Ouchterlony Valley I was unfortunately unable to visit, but from a view obtained of it from an adjacent hill I should describe it as a sheltered gently-sloping valley, clothed from end to end with dark green coffee which had every appearance of strength and vigor. In my visit to the S. E. Wynaad I did not cover a large area of cultivated land, but the estates I saw looked wonderfully well. The elevation of this plateau being some 2,000 or 3,000 feet above sea-level, the character of the coffee differed from that on the higher ranges of the Nilgiris. Of the absolute necessity of shade for the well-being of coffee in this district I was speedily convinced, and the planters are keenly alive to it. Shade trees are selected with great care and discrimination, and in felling the forest all suitable for this purpose are left standing.

A much-prized variety is grown from seed in a curious and novel manner. The seeds are much sought after by ants which will destroy a whole nursery in a week, unless due precautions are taken. The plan adopted is as follows:—A small "pandal" is constructed of sticks about three feet high, and upon this soil is laid some four inches thick, and in this the seed is sown. An indigenous tree of the "Ficus" family is planted thickly in young clearings in the form of cuttings, and later on these are thinned out at the planter's discretion.

Some of the fields had borne heavily this year, and where good shade existed gave promise of an equal yield in the coming season. Much anxiety was felt and expressed about the March blossoming showers. Given these at the right time, good crops were considered more or less certain. Leaf-disease was more conspicuous in the Wynaad than in Coonoor, but I was informed that the trees suffered from only one severe attack in the year which acted as a "wintering" and was beneficial to them rather than not. A convincing proof that the cultivation of coffee is remunerative in these regions lies in the fact that new clearings are being opened. Young plants looked strong and healthy in spite of a long drought, and, as great judgment is exercised in the selection of fields for these extensions, I see no reason why the S. E. Wynaad planters should not have a prosperous time before them.

Land and labor are cheap and abundant. Large herds of buffaloes are available for manure, and their value is duly appreciated. As an instance of what coffee has done in the S. E. Wynaad, a field of 70 acres was pointed out to me, near Nellikotta, which had recently given a crop of 85 tons of coffee.

The trees still retained much strength and vigor, and, though they may never do it again, they were far from "throwing up the sponge."

The jungle on most of the best land takes the form of bamboo clumps, with here and there, magnificent teak trees and bastard ebony intermixed.

Sholas or ravines are selected and ridges and rocky slopes are left untouched.—Ceylon "Times."

PLANTING IN NORTH BORNEO.

To the Editor of the "British North Borneo Herald."

SIR,—A letter I wrote to a planter in Ceylon has been published in the *Ceylon Observer* and also in the *Tropical Agriculturist*. Had I imagined this would have been done, I should not have written to the said Planter at all.

I think it might be as well to give some details of planting in British North Borneo for the benefit of hard-working planters with little capital in Ceylon or elsewhere, who may think of planting Coffee in a land of no leaf-disease, and I shall be much obliged if you will publish this in the *Herald*. The letter I wrote, though quite correct for the person to whom it was written, is very misleading, as far as information on planting goes, to the general public. No planter should come here with less than \$7,000. 1 dollar is 2 1/5 rupee or three shillings at exchange; he must also be prepared to be in the field all day, and have no assistant. A man with that amount, who is willing to work hard, can make himself independent in a few years, but he must remember that it is no holiday work. Men with £3,000 or £4,000 could get their work done easily and have as many comforts as they like. Forest in British North Borneo extends to the beach, there has been no coconut planting by natives, except here and there, because the coast used to be infested with pirates before the days of steamboats. Good land can therefore be had within easy distance of a shipping port. The price of land has been raised to three dollars per acre, owing to the success of the tobacco planting and other things. There is no Coffee estate except mine, everyone who has seen it however is much pleased with it; there will be a few bushels ripe soon, and the trees are full of small berries, and are always blossoming. I have 20 acres 2 years old, 12 one year, and 50 just planted. A Coffee planter from Java has begun felling on the other side of the bay from Kudat. Kudat is in Marudu Bay, the most northerly part of Borneo. There is a large acreage of land suitable for Liberian Coffee, Cocoa and Pepper, and seed and plants can be had of all from the Government garden at Silam. All one has to do is to apply for land, look for it, pay for it to the nearest Government Officer, and start at once. The labourers are native—they come from Padas, Brunei and Sarawak. I had a lot of trouble at first, as I did not understand the people, nor the seasons of the country, and could not speak Malay and a lot of money was wasted: those troubles are now overcome, and if any planter comes here, I can tell him what to do, and what not to do, and save him from buying the knowledge. The Borneans are better coolies than the Tamils, they have more sense and are more manly, however we will have to get Tamils to pick large crops, as natives will only engage for from 4 to 6 months, then go away. They do not bring their women and children with them, but they work regularly, and have no rows. They all carry a cutlass called a parang, which they keep in a wooden sheath, the blade is about 18 inches long, and has a small wooden handle; it is a most useful weapon, and they use it for nearly everything, and what is better they buy it with their own money. They have no Gangan, I deal with each man by himself. This however is easily done as one man if sent to do a bit of work at a distance, does it as he is told to do, and returns whenever he is finished. In felling I work with my coolies, they first cut the small wood then the large, and do not lop, as it is not necessary. I stand with them all day, felling and making the land ready for lining costs \$450 per acre. The men cut 2,000 lining pegs and finish early. I get 60 large holes from them which they finish by 2 p. m., some cut more and get paid extra; but most of them are pleased with the 60. There is a capital tool here for holing, it is a sort of spoon, nearly semi-circular, something like the thing grocers use to put sugar into scales; it has a handle, made of wood by the Cooly who is to use it, and it scoops out a good hole in no time. In filling in, the Bornean does much better work than the Tamil; he does not put in sticks and stones or purpose to fill up the hole quickly. Planting here has to be done more carefully than at high lands, as the sun is very powerful; I always have to shade the plants with branches of trees, and carry the plants in plantain leaves. Clearings must be fenced round about, as deer eat the young plants: they bite off the tips of plants and young branches, older trees they do not seem to care about. The coolies make the fence of jungle

sticks only, which keeps out the deer, they don't try to break it. A man does a chain a day, so it is not expensive. Weeding must be done twice a month. I get two acres each time per man per day; they also pull off suckers, it costs 30 cents per acre per month, I give no contract, but stay with them all day. Wages are 25 cents per day, but as the coolies are all men, and I have no canyau, it pays well enough. Bungalows and lines can be built cheaper here than anywhere I know of. This estate is three miles from Kudat a shipping port, so I can put my crop on board ship for the same price as I used to put it into carts on the Government road in Ceylon, and thus save the cart hire of 23 miles and railway carriage of 90. Rice is cheap here, but I supply the coolies with nothing. I pay them every second Saturday instead. When I came here first, we were almost out of the world, now we have four steamers a month. One of the steamers goes to Hongkong, it sails from Singapore, touches here and at Sandakan, and then goes on to Hongkong. We get fowls, sheep, &c., from there cheap, and if one requires a change and has not much time to spare, the trip from here to Hongkong and back only requires twenty days including a stoppage of four days at Hongkong. There is a fairly good breed of cattle here, and they are not dear. Those who like shooting can get lots of it. There are Sambur deer, red deer, pigs, wild cattle, elephants, bears, alligators, and birds of all kinds. There is a mountain here called Kinabalu, which is 14,000 feet high, it is about 40 miles from the bottom of this bay, people who have been there say there is a large extent of fine land suitable for Arabian Coffee, Tea, and Cinchona, all around it, at an elevation of from 4,000 feet and upwards. I have not been to see it but am going soon.

Yours truly,

P. CHRISTIAN.

Kudat, 17th January, 1889.

COCONUT CULTIVATION.

FUMIGATION.

On reading the *Observer*, I learnt for the first time that the great apostle of smoke for coconut trees has left behind him many followers, and that their number is increasing. My excuse for my ignorance of what is going on around me, and in a branch of my profession, is that I am to a great extent a hermit. My contact with the shining lights amongst Coconut Planters is not frequent, and is almost always through the Press. Beside, I am a resident in a sleepy hollow, where Coconut Planters are so weighed down by leaf-disease, a hard, dry soil overlying a slab-rock formation, and a peculiar susceptibility of their trees to annual drought, that they are unequal even to the exertion of smoking their trees. These living in a kind of Israelitish camp amidst plague-stricken Egypt—where they enjoy a special immunity from plagues, and having as owners of properties distinguished sons of the soil whose names are as household words along the length and across the breadth of the Island, and who have for their leader a veteran and very progressive Planter, and with so fertile a soil that nails sown in it soon grow into Alavangus—can well indulge in the luxury of "ploughings annual and oftener" for their coconut plantations, with bones applied *ad lib.*, and last, though not least, a good smoke.

I would not have felt myself called upon to discuss this question, but for a reference to me in the communication in question, where my opinion on the subject is mysteriously hinted at, and not fully set forth and discussed. I am told that it would have been easier for me to deny that smoke did any good to Coconut trees, than to say it may benefit them indirectly. Doubtless a simple and bare denial would have been easier, but I avoid dogmatism. I always prefer discussing a question in all its bearings, and setting forth the *pros* and *cons* fairly. That is more likely to convince a sceptic than a mere denial, and is also the proper way to approach a scientific question. "Old Planter" has been long before the public as a teacher of Agricultural Science, but that his teachings do not meet

with much recognition is owing to a bad habit he has of speaking contemptuously of those who are not in agreement with him, and of not dogmatizing. What right have we, who are empirics at the best, with but a smattering of agricultural knowledge, who have never been working in a laboratory, who have carried out no scientifically conducted experiments, who have but the vaguest knowledge of vegetable physiology, to decide authoritatively on a question outside our ken?

Let us now consider this question fairly and dispassionately. To begin with, what *is* smoke? It is the moisture contained in a substance that is burnt passing off in the form of vapour. We all have observed that the more moisture there is in a substance burnt, the denser the smoke, and *vice versa*. When a substance is subjected to the action of fire, which is a quicker method of decomposing it than by natural means, the organic portion of it is dissipated. Therefore, there will pass off with the smoke a quantity of carbonic acid and ammonia. Agricultural chemistry teaches us that all plants are composed of organic substances, supplied to them from the atmosphere, and inorganic or mineral substances drawn from the soil. We are further taught that leaves absorb not only carbonic acid, as "Old Planter" asserts, but also small quantities of ammonia, and both these substances form the organic portion of all plants. Carbon, which is derived from carbonic acid, plays a very important part in the structure or composition of the plant. The question now resolves itself into whether the absorption of carbonic acid by the leaves is dependent on the supply; or in other words, whether they take up all or mostly all supplied to them by fires burned underneath them. This is a subject on which non-professionals cannot express an *ex cathedra* opinion. In a conversation with the new Head of the Agricultural School, I discussed this question with him. I asked him if it was possible by increasing the supply of carbonic acid by fires under our coconut trees to increase the demand for it, and whether it was possible that the stomata of the leaves became distended and more receptive by the action of the fire, and therefore took in larger quantities of carbonic acid than under natural circumstances. He said he did not think so. I also told him that the late Mr. Carry of Kimbulpitiya asserted in a communication to the press that he increased the number and size of his nuts more by smoking his trees, than by the application of the best manures; and that my contention was that if such good results *did* follow smoking—"vaporization" as he termed it—they were due more to the mechanical and chemical changes in the soil by the action of fires and to the residual ashes than to smoke. He agreed with me.

To test the efficiency of smoke, it will be necessary to choose a field of Coconuts without a habitation on it, and to burn fires in furnaces well away from the ground, and not apply the ashes to the soil. I think an experiment conducted on these lines will cure the most enthusiastic believer in smoke by its inefficiency.

Now that I have indicated the opinion of the present Head of the Agricultural School on this subject, I hope "Old Planter" will not clamour for the School being closed.—B.—"EXAMINER."

THE COCONUT LEAF DISEASE.

The *Observer* has a few remarks on my communication on the above subject which I propose to discuss.

To my thinking there is a vast difference between Dr. Trimen's "innutrition" theory, and my theory of "a disease caused by innutrition." His referring me to the roots and the soil to find the cause of the disease led me to regard the word as synonymous with "starvation," caused either by an insufficiency of roots or by a poor soil. I look upon the disease, not so much as a vegetable "parangi," as a vegetable "scurvy." Medical men are, I believe, unanimous in their opinion that this latter disease is caused by the absence in the dietary of human beings of one essential constituent of food. Give human beings food in any quantity abounding in all the essential constituents of food save this one, and scurvy will be the result. Was not the scale of the dietary of our jails raised to its present attractive

proportions owing to the report of medical men that scurvy resulted from an insufficiency of nitrogenous food? I say, that the natural home of the coconut palm is by the sea-shore, and in a soil impregnated with salt. By cultivating it in inland districts, it is not grown under natural conditions. Salt is a dominant constituent of its food, and its cultivation in soils with an insufficiency of salt renders it liable to disease. Why, it may be asked, did not disease show itself before now, considering that coconut cultivation in such soils is not an industry of yesterday? We know that certain conditions are necessary for the development and spread of disease. Medical science teaches us that insanitation leads to certain diseases. Insanitary surroundings help to the outbreak of sickness only when the conditions for its development are favourable. To take a more apposite example, old Planters have certified that they were acquainted with coffee-leaf-disease for over a score of years before it arrested attention. They thought nothing of it, as it did no harm. Dr. Thwaites said that the fungus existed for long in the jungles, before it found a congenial home on our Coffee trees. What were the conditions that favoured its assuming an epidemic form and attaching itself to Coffee? Opinion are divided on this point. Scientists say that the conditions were the violation of a law of nature that is abhorred large expenses of any one product. The disease vindicated that law, but has disease left the Coffee plant now that the balance of nature has been righted? Most emphatically no. Wherever a Coffee plant is, there will the fell disease be found. Others say that the causes of leaf disease were climatic, others again atmospheric, and that there is a something in the climate of the hills now inimical to the growth of fruit, but favourable to the growth of leaves, and is the atmosphere favourable to the growth of the deadly fungus. As everything mundane is governed by cycles, the old climatic and atmospheric conditions will re-appear. This belief has the merit of being consoling, but what are the grounds for it? Eternal Hope.

May a merciful Providence guard coconut trees from such a visitation! Where, in the European, failure only helped to bring out in bold relief his innate qualities of determination and pluck, the Oriental may be overwhelmed and paralysed with despair. This coconut leaf disease is no new thing. Every coconut tree, more or less, has its leaves discoloured by spots. I had plant with their fronds looking as if fire had passed over them for many years back, and they attracted only passing attention. This year I saw an aggravation of these spots and a large number of trees affected, but even then it caused me no alarm, till meeting a gentleman in Colombo at the end of January, whose duties took him into the country in a radius of about 20 miles of the capital, he asked me if I had noticed a peculiar affection of the coconut leaves. He met it everywhere in his journeys in the country. I then knew for the first time that the affection was not local, and on a further and careful examination of my trees I was impressed with the severity of the attacks of the disease. As I noticed fungus in the withered spots, I thought the affection fungoid: Dr. Trimen thought fungus only an effect. The subject absorbed a good deal of my attention, and I came to the conclusion that the disease was probably due to a want of salt in our soils, and was possibly developed by the abnormal weather of last year. Mr. Jardine, a very experienced and intelligent Planter, after a visit here was of opinion that our stiff soil was the cause of the affection; that during dry seasons the roots were earth-bound and inert and supplied no nutrition to the tree. This caused the sap to be diseased, and probably sweetened, and invited an attack of bug. The remedy he suggested was a thorough working of our soil. He apprehended a cessation of the attack when the rains fell and favoured the passage of the roots through the soil. In refutation of his opinion that the mechanical condition of the soil was responsible for the attack, I pointed out to him trees growing in a free soil attacked, and I can even now show large trees in bearing, growing on a perfectly free soil, with their leaves punctured. He asked me to water a plant and break up the soil round it thoroughly and watch results. I did this to four

plants, breaking up the soil to the depth of one foot, and applied half a basket of lime each to the two most affected, and a basket each of ashes to the other two. I watered them subsequently and shaded the portion of the soil dug up, which by the way displayed no lack of apparently healthy roots. I was not convinced of the wisdom of breaking and disturbing the roots during the dry season, but the respect I pay to experience made me do it. Happily any damage done will be minimized, for we have had abundant rain since. To two trees I applied half a measure each of salt after simply scarifying the soil round them to prevent the water, I subsequently applied from running over the hard-baked ground. As I said, rain has fallen since, and the effect of these different modes of treatment cannot be accurately gauged. Mr. Lamont is, as usual, enigmatical in his opinion of the cause of the affection.

I wrote to Dr. Trimen a second letter inviting him to investigate the disease on the spot and giving him Mr. Jardine's and my theory of the disease. I enclose his reply, as I presume he will have no objection to its being published, as it is of public interest:—

"I scarcely think that the mal-nutrition of your trees—to which I attribute the dead spots in their leaves—is due to want of salt in the soil; unless indeed the land where they grow is quite abnormally wanting in this almost invariable constituent (which might be determined by an analysis). I should rather look to the physical properties of the soil, and especially to the drainage. I know, of course, nothing practically of coconut cultivation as a speciality, but should expect that the ordinary rules of treatment applied, and should certainly in your case give the soil round the trees a good thorough forking and perhaps a basket or two of manure to each tree.

"That the mortified spots may be set going in the first instance by the punctures of a minute bug is by no means improbable. Its proof or disproof is simply a matter of careful and prolonged observation, and a few sharp little native boys would be the best persons to put on the work with instructions to catch everything they see on the leaves.

"So far as I have seen, I am not disposed to consider these spots a very alarming phenomenon. They are pretty frequently to be seen on all palms if not in a quite healthy condition, and I quite expect that under a more liberal treatment they will cease to appear. Before deciding to come and see the trees, I shall prefer to wait for your further report."

It will be borne in mind that my contention all along has been that the soil here possibly has an insufficiency of salt, not an entire absence of it. As I have said before, trees growing both on stiff and free soils are attacked. As to drainage, I venture to think no coconut estate in the Island in upland districts is trenched so thoroughly and systematically as this is. This is a speciality with me. I may mention that I dug round the trees of this estate every other year, but as I believe the roots of the trees have advanced considerably outside the circle I have been wont to dig up, I discontinued the practise last year as likely to do more harm than good. I am of opinion that a very large circle round the trees must be forked, or the whole soil must now be broken up; but this is a work I can only recommend. I am willing, nay will be glad, to believe that the attack is due to bug, as I would much rather fight an insect than a fungoid enemy. It is certainly consoling to hear that the disease need cause no alarm, but I would have been more gratified if the good Doctor expressed this opinion after visiting an affected Estate. As to liberal treatment, I can point out to him a tree which received in October-November, 16 baskets of cattle manure and one basket of ashes dug round it, as severely affected as any tree. This tree is a weakly specimen growing in a pretty stiff soil. I can show him another tree, a large one, growing in a very free soil and which had 3lb. castor cake, 1½lb ground bones and 1½lb kainit in July last also affected. In this instance the soluble salts had evidently been washed out of the soil during the heavy rains of the N-E. monsoon and before the tree was able to take them up by forming new roots,

and others that had two head of cattle tied at their roots for over a fortnight and their droppings dug into the ground with 1lb bones and one basket ashes. How is that for the innutrition theory? No, this is a matter that cannot be decided at a distance. We want a chemist and one who has made agriculture a study to investigate it on the spot, and as soon as I saw the announcement of the arrival of Mr. Driberg the newly appointed Superintendent of the Agricultural School, I wrote to the Colonial Secretary asking for his services to investigate this disease.—"Examiner."

ROYAL GARDENS, KEW.

(From the Bulletin of Miscellaneous Information.)
FIBRE INDUSTRY AT THE BAHAMAS.

Colonial Secretary's Office, Nassau, N.P., 22nd November 1888.

I am directed by his Excellency the Governor to call your attention to the important question of fibre cultivation, now so largely engaging the minds of the public, and on which it is essential that the fullest information should be disseminated.

During his Excellency's late absence from the Colony, he was enabled to gather some instructive particulars, which strengthens his faith in the part the fibre industry is to play in the speedy advancement of the Colony.

Through the good offices of the Crown Agents for the Colonies in London, the following statement was obtained from Mr. Thomas Briggs, a gentleman of great authority, to whom a sample of rough rope from Bahamas fibre was submitted for examination. Mr. Briggs states, under date September 3rd, 1888:—"This material I consider equal to very good Manilla hemp, and worth in the unspun raw state thirty-six to thirty-eight pounds per ton, colour excepted, which is not of very great importance. I consider it to be a very superior article for spinning in yarns for ropemaking, and unless in bulk some ingredient should be found to counteract its apparent good qualities, it should find a ready sale at the price I name."

This testimony is highly satisfactory, and in the United States the article is not less fully estimated. It is, moreover, a staple commodity of commerce in which serious variations of value are not to be looked for, and this goes to rid the work of production of uncertain and risky conditions.

With land and climate so adapted for the growth of the Sisal fibre, the plant being indigenous, it is remarkable that the industry had not acquired a practical existence until the Legislature gave it an impetus by the fostering Act of the Session of February last—so little was it generally regarded that the small farmers viewed the plant with despair as a noxious weed they were unable to eradicate. From every part of the Colony we now have gratifying proofs of an awakening and intelligent spirit and of the steady advance in the establishment of the industry, and public faith in its efficiency as an agent of general future prosperity increases as we proceed in the work of inquiry. There are some very interesting statements in a pamphlet recently published by Mr. Stoddart, of Jamaica, who spent some time in Yucatan, where the fibre industry has for some years been prosecuted with conspicuous success, under conditions of soil and climate not more favourable than we have in these islands. We were aware that the plant is independent of drought, and this is Mr. Stoddart's experience. It was also believed in this Colony that it takes about three years after planting to bring the leaf to a productive state, and this is confirmed by Mr. Stoddart, who also affirms that it will then yield annually for 15 to 20 years without any material outlay on its cultivation. The produce of an acre in full growth Mr. Stoddart sets down at from one thousand to twelve hundred pounds of fibre, and he corroborates the opinion held here that the plant thrives best on rocky and impoverished soil, and that it is shunned by cattle, and consequently free from injury on this account.

Mr. Stoddart's estimate of production, which it is not meant to impeach, admits of a large abatement

and yet leaves the enterprise full of promise. At a fair price he makes the money value of an acre about eighty dollars annually, but His Excellency prefers a lower basis of calculation to cover all assumable adverse contingencies. The Governor in this view takes fifty dollars an acre annually, which gives a handsome margin of profit on the cultivation. The return of wheat farming is highly enough placed at 35 bushels an acre, or as many dollars at a reasonable computation of price, and we are thus brought in presence of the extraordinary conclusion that the barren lands of the Bahamas, through the fibre cultivation, are made to bear an economic value beyond the favoured wheat-growing regions of the United States and Canada. We moreover find this difference enhanced by the fact that the fibre needs but one planting for 15 to 20 crops, while wheat must be planted annually, and is liable to many injurious contingencies from which the Sisal plant is exempt.

These islands should be the Paradise of the working man. The land is obtainable on very easy terms, and in lots to meet the circumstances of the labouring population. To create the largest possible number of peasant proprietors is the great desire of the Government. But it is not their intention to lead the people away from their present pursuits, for the new industry can be combined with those existing, as it will involve little more than the use of the time now left on their hands. There are nearly 2,000,000 acres of ungranted lands in the Colony, and with the conditions of purchase, the facilities for prosecuting the fibre cultivation and its value as a staple article of commerce, the countries are few that offer so fair a field for the reward of the capital and labour that may seek investment in this undertaking.

It is intended immediately to despatch a Commissioner from this Government to Yucatan to make further inquiries, as it is of the utmost importance to have the fullest information on the whole economy of the industry, in which the people of this Colony are now so vitally interested.

Mr. Stoddart's report (published by the Government of Jamaica) on which the estimates of profit in Mr. Taylor's memorandum are based, was communicated by Kew to the Colonial Office for transmission to the Government of the Bahamas in reply to a despatch from Governor (Sir Henry) Blake, dated 24th January 1887.

It was pointed out at the time in par. 5 of the Kew letter, dated 15th February 1887, that "the statements contained in the pamphlet are not necessarily endorsed, either by the Government of Jamaica or by Kew. It professes to be nothing more than an account given by a Jamaican resident of the fibre industry in Yucatan in which he was practically engaged for some time."

It is to the credit of Mr. Stoddart, however, that his account of the fibre industry of Yucatan is confirmed in most particulars by other writers, and there is no reason to believe that it requires correction in any essential part. It may at the same time be desirable to point out some of the conditions under which the industry is remunerative in Yucatan.

For instance the rates of wages in Yucatan are comparatively low (ranging from 9d. to 1s. per day for labourers), and under such circumstances, Mr. Stoddart estimates (at page 10) the net profit on current expenses at "between 4l. and 5l. per acre" (equal to between 20 and 30 dollars per acre). The plants, if 18 inches high when first put out, are said to be ready for a first cutting in three years. This period may, however, under unfavourable circumstances, be prolonged to five or six years. Another important point to bear in mind is that Mr. Stoddart speaks only of returns obtained by the use of machines driven by steampower, and by working plantations of say 100 acres or more. The methods suited to one country are not necessarily suited to another. Possibly at the Bahamas it might be advantageous for small cultivators to clean the fibre in their leisure hours by hand, and sell it locally to merchants who would ultimately undertake the business of baling

and shipping it. If the fibre is not properly baled, the cost of freight would be so large as to greatly reduce the returns. Indeed the fibre in a loose state is so bulky that it would be almost impossible to ship it at such a rate as would enable it to compete successfully with fibres from other countries. It is usual to pack this class of fibre by means of hydraulic presses, in bales of about 400 pounds each. If the small proprietors in the Bahamas take up a fibre industry, it is evident that some one possessing capital should be prepared to purchase the fibre in small quantities and pack it by means of suitable presses ready for shipment. There are no grounds, however, for supposing that a fibre industry based on *Agave* and *Furcraea* plants, and judiciously pursued, can be otherwise than satisfactory.

A collection of fibre plants was received at Kew about two years ago from the Government of Bahamas, and it was stated in a letter dated the 16th May 1887, that among these specimens there is no species exactly answering to that yielding the Sisal Hemp of commerce. The fibres of No. 2 (*Furcraea cubensis*), and No. 3 (*Furcraea cubensis*, var. *inermis*), are the most valuable, and these are used partly as a source of commercial fibres in Yucatan. The true Sisal Hemp plant is *Agave rigida*. This may be abundant in the Bahamas, but no specimens were received of it. Other fibre plants received at the time mentioned were *Agave lurida* and *Agave americana* var. *variegata*, the latter a variegated form of the common American *Agave*. These latter are of little value for fibre as compared with the true Sisal hemp plant. Specimens of African bow-string hemp (*Sansevieria guianensis*) were also received, the fibre of which is of high value.

A fibre industry has been in existence in Mauritius for some years. The experience gained there might be of service in the Bahamas, especially in regard to the initial difficulties to be overcome in establishing a new industry.

The market value of this class of fibre, and the permanency of demand for it, has been fully investigated at Kew, and in a note on p. 3 of the *Kew Bulletin* for April 1887, there is a summary furnished by Messrs. Ide and Christie, which gives the average price per ton for Sisal hemp in London for the years 1879-86 inclusive. These are 1879, 27l.; 1880, 27l.; 1881, 28l.; 1882, 28l.; 1883, 27l.; 1884, 21l.; 1885, 19l.; 1886, 21l. The highest price paid was 32l. 10s. 0d. in December 1879 to February 1880, the lowest price was 17l. 15s. 0d. in January and February 1886. Recently there has been an increased demand for white fibres, with a corresponding rise in prices. There were no quotations for Sisal hemp in Messrs. Ide and Christie's London Monthly Circular for December 15th, 1888. The only remark being "in retail supply, and selling at fancy prices." In the United States, Messrs. Crocker's statistics, dated the 1st December, gave the price at 8 to 8½ cents. per lb. (equal to about 37l. to 39l. per ton). A rough *Agave* fibre from Bombay (probably prepared by hand) was valued last December at 15l. to 17l. per ton. Mauritius hemp prepared by machinery from *Furcraea gigantea* (known as the green aloe or green *Agave*) was valued: good, 34l. to 35l. per ton; fair, 33l. per ton; common, 30l. per ton. D. M.]

HARDY SPECIES OF EUCALYPTUS.

It is well known that some species of *Eucalyptus* are hardy in certain districts in this country, but the ordinary Blue Gum, *E. globulus* is only sparingly so. We have recently received from Mr. F. Abbott, Superintendent of the Botanic Gardens at Hobart Town, Tasmania, a small quantity of seed of this species collected from trees growing at high altitudes and exposed to severe frosts. Seeds were also received of *E. coccifera* from trees which were coated with icicles "a foot long." It is probable that plants raised from seed of such hardy forms would be likely to bear with impunity the rigours of an English winter. The seed received has all been sown and the results will be duly noted later. In the meantime the following extract from a letter received from Mr. Abbott will be read with interest:—

In the same package I put a little seed of *Eucalyptus Globulus* from Tullochgorum, a part of the Colony where the winters are severe, and on that account the plants raised from the seed forwarded are likely to withstand an amount of cold that would kill the ordinary form, at all events it is so here, as all attempts to introduce the plants into the district from the southern parts of the island failed, the cold proving too severe. Eventually a few isolated plants of *E. Globulus* were found growing in a sheltered gully some 20 miles from Tullochgorum. These were the only plants of the species that have been found growing naturally in so cold a climate, and plants raised from these trees were planted about Tullochgorum, and grew into large trees, without ever suffering from the severe frosts so prevalent in the districts which has always killed plants brought from the warmer parts of the island. It would therefore be well worth while to give any seedlings you may raise from the seed sent a fair trial, with a view of proving whether this particular variety is sufficiently hardy to withstand the cold of an English winter. It will not be possible to obtain much seed, but any I may get I will forward to you, as you will have a better opportunity of testing it. I have a little more drying out which will be forwarded as soon as it is ready. I send with this a little seed of the hardy *E. coccifera* which I have seen on the top of Mount Wellington completely coated with ice, and shielded with icicles a foot or more long hanging from the branches. I have no seed of *E. verrucosa* at present, but will get some as soon as possible. This is a very dwarf species, usually under 4 feet, and at best is very sparing at producing seed. I have no doubt it will be hardy.

WEST AFRICAN RUBBERS.

REPORT OF THE INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS COMPANY, LIMITED.

Silvertown, 21st July 1887.

Description &c.—Four samples of India-rubber were received, marked respectively No. 2, No. 3, No. 3 (dark), and No. 5.

The samples marked No. 3 have been dealt with as duplicate samples of the same rubber. Sample No. 2 was black and sticky on the outside due to oxidation, the freshly-cut surfaces were slate-grey colour. The rubber was firm and non-adhesive to the fingers. The samples marked No. 3 differed slightly in appearance, one was much darker than the other. The darker sample evidently would be more prone to decay than the lighter sample, but still both samples are remarkably good for African rubber. Both these samples consisted of agglomerated tear-like masses, with red and pinkish particles strongly resembling rubber. Evidently, if these samples are from the same plant, the difference in colour of the tears must be due to the incision or puncture extending to different tissues. The light-coloured particles were very similar to good Ceara rubber. The freshly-cut surfaces of sample No. 5 were whitish in colour. It was very similar to the better specimen of No. 3, and as a raw article is quite equal to the best kinds of Brazilian rubber. On so small a sample, it would be difficult to say how it would behave in general manufacture. The behaviour of a specimen under manipulation is of primary importance in fixing its commercial value. However, this specimen is far above the best kinds of African rubber.

In Manufacturing, &c.—No. 2 lost 145 per cent. on washing and drying, becoming sticky and of course difficult to treat in the ordinary way. In quality it is very low, being inferior to flake African. Mixed with a suitable proportion of sulphur it vulcanized fairly well and free from sponginess. It would hardly be suitable for working by itself, but with firmer kinds of rubber it would mix well and yield a product suitable for many low class manufactures. The two samples marked No. 3 lost 5.6 per cent. on washing and drying. The samples were mixed together and behaved very well in grinding and mixing. It vulcanizes very well in being elastic, firm, and

solid. In this stage it takes a dark colour, but is not offensive in smell.

No. 5 samples give a loss of 8 per cent. on washing and drying. It vulcanizes very well, although dark in colour. Its smell is not offensive but strong.

Remarks.—As a rule the African rubbers give dark products on vulcanizing, and many of them have an offensive odour, which arises no doubt from the action of sulphur, in vulcanizing, on some principle contained in the natural sap of the plant yielding the rubber.

Messrs. Taylor, Laughland and Company, of Glasgow, recently forwarded specimens of West African rubber with a letter of which the following is an extract:—

One of our agents in Old Calabar, West Africa, has collected and sent us a few samples which he is very anxious to get classified, and thinking that you would help us in this, we have sent to-day to your address per Globe Parcel Express, carriage paid, a parcel containing these samples as per enclosed list. He is anxious to get the natives to cultivate the rubber vine and make rubber more freely. He says he has been up the country and finds the various kinds of rubber vines in great abundance, but no rubber is taken from them, as until quite recently the natives did not know that there was any value in it, and even now they do not know how to make the rubber from the juice. In order to teach them and secure the best plants, he has sent home specimens of the leaves of four common kinds of vines with the native names, and if you can give us the scientific names we shall feel much obliged. He sends also the rubber from them, but, as you will see, it is very badly made. Can you say which is the most valuable of these four vines?

Three of the four specimens sent were wholly inadequate for any determination. But one called Npok was identifiable as *Landolphia owariensis* which is found from Sierra Leone to Angola, and is no doubt the most important source of West African rubber. [See Kew Report for 1880, p. 38]

An investigation into india-rubber milk received at Kew from the Niger delta is described in the following correspondence:—

38, Elthiron Road, Fulham, S. W.,

DEAR SIR,

14th September 1888.

Several gentlemen to whom I have applied for information about india-rubber have recommended me to communicate with you. I therefore venture to ask if you can help me, and trust you will pardon me for intruding on your valuable time. To explain myself fully, let me say that I have for some years been trading on the West Coast of Africa, in the oil rivers (the deltas of the Niger). For some time past we have been endeavouring to introduce and foster the india-rubber trade, and have been partially successful. There are quantities of rubber trees and vines, but the natives of these districts, having hitherto never cultivated the article, are quite ignorant of the mode of preparing the milk obtained from these trees and vines to convert it into a commercial form. We are quite certain that this matter will open a wide field of commerce to the benefit of the native, the trader, and the consumer, if we could learn the mode of treatment. What I wish to ask you is if you can inform me of the best mode of congealing the milk as it is obtained from the tree. Accompanying this I send you a small sample of rubber milk in its natural state. Should you deem it worthy of your notice, I will most gladly furnish you with a large sample for experimental or other purposes.

I am, &c.,

(Signed) James S. COCKBURN.

W. T. Thiselton Dyer, Esq.,
Royal Gardens, Kew.

ROYAL GARDENS, KEW, to Mr. JAMES COCKBURN.
SIR, Royal Gardens, Kew, 2nd November 1888.

I beg to forward herewith a copy of a report received from S. W. Silver, Esq., F. L. S., on the sample of rubber milk from the Delta of the Niger which you recently forwarded to this establishment.

2 I regret to notice that this substance is not of a character likely to be used in commerce, and the results of the experiments are such as preclude any hope of solving the question of coagulating the milk in a satisfactory manner on this side.

3. If we had specimens of the leaves, flowers, and fruit of the tree from which the milk was obtained, we might then be in a position to suggest a treatment that would afford satisfactory results. At present we have no data upon which to work, and the matter cannot be carried any further.

4. We would suggest that steps be taken to procure specimens of leaves, flowers, and fruit of all rubber plants in the district in which you are interested and we enclose instructions for collecting and preparing such specimens, so that they might arrive in this country in a suitable state for examination.

I am, &c.

(Signed) D. MORRIS.

J. Cockburn, Esq.

(Enclosure).

REPORT OF THE INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS COMPANY, ON SPECIMEN OF INDIA-RUBBER MIK from WEST COAST OF AFRICA.

Silvertown, October 26, 1888.

The contents of the tin were strongly acid; on pouring out the same it was found that the tin contained a large quantity of already coagulated gum, which could only be removed by cutting off the lid. The part coagulated was treated by itself. The portion still liquid was emptied into open dishes, so as to cause a further separation of coagulum by evaporation. The portion which separated in this case was treated by itself. Both products were very sticky, and became more so as the washing process was continued; they ultimately became quite unmanageable for the subsequent stages of drying, &c.; the substance is quite unsuited for any ordinary india-rubber manufacture.

By destructive distillation it does not yield caoutchouc, which is the principal characteristic of caoutchouc or india-rubber. The distillate more closely resembles in smell that of some principles, balsams, &c. which yield cinnamic acid. This is highly characteristic and of value in determining the suitability of a lactescent juice as a mercantile source of caoutchouc. The most suitable way of obtaining the coagulum from this juice is by leaving the same exposed in open vessels, and collecting what forms on the surface from time to time so as to increase the chance of further evaporation, &c. If it be intended to send these natural juices for examination it will be best to add ammonia freely, so as to neutralise any acid which may be generated whilst in transit.

The Resident Manager adds: "We do not see our way to make use of this material. We quite agree with your remarks to Mr. Morris as to the chemical change in these juices that takes place before they can arrive in this country."

MEETING OF THE LINNEAN SOCIETY.—At the last meeting of the Linnean Society, Mr. Morris, the sub-director of the Government Gardens at Kew, exhibited an interesting collection of wood, showing an unequal distribution of silicate in certain parts of the tree, especially in teak. His view was that the deposit consisted of phosphate of lime. The formation of gums, resins, &c., and the properties taken up by the trees for their nourishment is not yet understood, much less the cause and reason for deposit of mineral matter in certain parts of the tree. Mr. Morris also exhibited from the rich museum at Kew another specimen, showing the singular solid mineral properties of a pearl from the interior of a coconut. These are always looked for by the natives. The nuts are broken after being placed in heaps until the eye shows signs of growing, for at this stage the milk or liquid has become absorbed, and it is thought the yield of oil is larger than if the nut is treated directly it comes from the tree.—*British and Colonial Druggist.*

WINDMILLS AS MOTORS IN CEYLON:

HOW PLANTERS MAY YET BE BENEFITED BY WINDMILLS.

A recent reference in these columns to past attempts made to utilize the force of the wind for obtaining power in Ceylon has suggested some remarks on the subject from a gentleman of practical experience. He appears to doubt if the local condition can be favourable to the employment of windmills, though at first sight it would seem as if the steadiness with which our monsoons blow either from the south-west or north-east must render them specially applicable to our local demands for power. But that consideration—although doubtless possessed of some degree of force—must be much discounted by the fact of the long period of lull that is experienced between these two monsoons. Now to be effective, to be economically useful, it is a first condition that all sources of power employed should be permanent and in a certain degree unvarying. It is this prime necessity that has caused us to see disappear from our own mother-country the numerous windmills which, until the introduction of steam power on a popular scale, used to perform all, or nearly all, the operations requiring power. The steam engine can always be relied upon at any crisis to meet an immediate, perhaps, an unforeseen, demand, while in such crises it might well be that a perfectly still day would render a wind motor completely useless.

Such a disability must be of marked effect in the lowcountry of this island, but it has been urged that among our higher levels there is scarcely a day throughout the year during which there is not movement in the air by which a certain amount of motive force might be created. Again, however, anyone who has had experience knows how variable is the direction and force of the wind among our mountains, due to their conformation and other circumstances. Power is required for estates in immediate proximity to their stores or curing-houses, and the sites for these are generally selected in as sheltered spots as can be found. Consequently, no reliance can be placed on obtaining anything like a constant motive force such as would be a necessity for estate operations. These in the main, are the principal arguments that suggest themselves as adverse to the proposition that we in Ceylon are neglectful of one of the greatest sources of power in nature; and, did they remain wholly unbalanced by other considerations, due to the advance of modern science, they might be considered to be unanswerable and as furnishing conclusive reasons why we might leave unrecognized the advantages to be derived from a perfectly costless agency of force. But the modern science we have mentioned has of late years advanced with such rapid strides, and is promising at the present time an even more developed advance, that such arguments as are used above, may soon come to be of non-effect.

Of course, it cannot be forgotten, when discussing this topic, how important is the bearing of the apprehension so widely felt, that each year will greatly increase the difficulties already experienced in obtaining a cheap and adequate supply of fuel for engine power on estates. The solution of the difficulty will probably some day be found in the almost magic words "storage of power." To very many these words may be enigmatical, and yet we have simply to cite the ordinary daily operation of winding a watch to illustrate how commonly such storage enters into our every-day life. It is from the extension of this

principle by the discoveries of science that we feel we may well anticipate the day when, as in times past, the force of the wind, which now passes by us unutilized and almost unheeded, may again prove a fertile resource to all those who have to employ extra-matural power. There is already well-known to us one method by which from time immemorial almost, the power of the wind has been stored so as to insure its regular reproduction at will, namely the impounding of water pumped up by windmills to a level above that at which power is required to be developed. But as regards Ceylon the use of this method must almost always be prohibited by many varied considerations which need scarcely be discussed. A second method of more modern adoption is the storage of air under compression; but there are natural difficulties arising from the intense cold developed by air during its expansion from a high state of tension which must ever, it is to be feared, render this system of storage of power inapplicable to ordinary purposes, and a highly charged air-vessel will generally, besides, be a source of danger.

But the advance of science, to which we have referred, is now bringing us close to a system of storage to which we may believe none of the foregoing objections and disabilities will apply. We refer, of course, to electricity. We are aware that there is still a difficulty to be conquered,—that of wastage. Confidence is, however, felt that the day is not far distant when this difficulty will be entirely overcome, and then it is easy to foresee with what readiness the storage of electricity will lend itself to the complete utilization of wind power. A wind-mill is a machine, which, in a certain degree “goes on for ever.” It can be working, while we are sleeping, and at times when the use of the power it develops is not needed. If such a machine be applied to the driving of dynamos, the result to its working during the hours of rest, or when power is not needed to be drawn from it, could be stored to meet the exigencies of the periods when its motive force is operative. Once this is accomplished, we may expect to see windmills taking the place of the chimneystacks which are beginning to be dotted about in many of our hill as well as low country districts; and we may have thus a great natural power in reserve against the day when fuel shall have become so scarce that steam can no longer be an economical agent.

“CEYLON ADVERTISER” NOTES.

The marked success of the tea enterprise of Ceylon is making itself felt in a variety of ways in the great metropolis, and of this the Colonial Office authorities appear, by all accounts, to be made sensibly aware, according to reports that have reached us the Downing Street officials are literally inundated with applications from persons seeking concessions in one form or the other in aid of industrial undertakings for the development of the island's resources. To the present time, however, we are informed that the applicants, with but one exception, have failed to convince the Secretary of State for the Colonies of their ability to carry out their proposals even when supported by the sought for concession. We suppose that the one favourable exception to this rule is the Ceylon Tobacco Syndicate.

Our readers may have heard of the action brought by a Glasgow baker and confectioner against the Committee of the Ceylon Court at the Exhibition of last year for breach of contract, assessing his losses thereby at £1,000. It appears he had been given the promise of the committee to supply estates such as cakes, bread, &c., in the Ceylon tea house,

for which privilege he had paid a certain sum of money. At the close of the first month this concession was cancelled as being in contravention of a contract made by the General Committee with another firm. The baker sued the Ceylon committee, and was awarded by the Court £150. Against this he appealed, and the higher Court has given him £500—half the amount claimed, which will be met out of the general fund of the Exhibition.

Now that the cultivation of tobacco has attracted so much attention in connection with Ceylon, it may be as well that we remind our friends in that island that the enormous dividends declared by some Sumatra Companies have been the result of their placing on the market a specially fine quality of leaf suitable for outside wrappers of cigars. This fine leaf has been eagerly bought up for shipment to Florida and Virginia and some to Havana; but it should be remembered that the demand for this high quality is not without a limit, and like fine broken Pekoe, its supply may easily be overdone. In the island of Cuba there is but a limited production of very fine leaf of which true Havannahs are made.

We constantly hear it said that it is all very well for the manager of the Hoolankande Estate to boast of the high prices paid for his tea, but that not only it cannot pay with such a small yield per acre, but that continuous fine plucking is certain to exhaust the trees. We do not pretend to speak in regard to the latter point, but as regards yield per acre, although we have no data before us, we have been assured that the proprietor informs his friends that Hoolankande yields within 20 per cent. of any of the adjacent estates.

TEA WITHERING MACHINES.

A planter writes:—“I have got one of Greig's XL ALL machines here which is worked with charcoal and I like the machine fairly well, and it finishes off a fill of about 60 to 70 lb. half withered leaf in fifteen and twenty minutes; but I never use the machine when I can get a natural wither or even the help of the sun. But rather than keep my leaf three days in the factory when it begins to decay and stink, I prefer to use Greig's XL ALL machine, and besides it economizes space in the factory and the tea I made by the machine brought very nearly as much as the ordinary tea made in good weather. I have heard of one or two complaints about the fireplaces cracking, but considering they are made of brick and clay, I think they do very well and cost very little to renew. I should not use the machine for drying tea, as I don't think it does the work well, but does fairly well for rearing teas before packing. I think tea withered in this machine ferments quicker than when made by a natural wither.”

COTTON CULTIVATION IN CEYLON.

We understand that the natives in the Matale district are likely to take favourably to the cultivation of cotton, especially if it can be cultivated along with their kurakkan, and there is no reason why it should not.

It may be information to some of our readers to know that nearly all the South Sea Islands cotton used for manufacture comes from the Southern States of the American Republic.

A HINT TO NUWARA ELIYA RESIDENTS.

It is as well for your upcountry people to know that peaty waters, or waters charged with vegetable matter, have a considerable solvent action on lead. This, of course, means that they are poisonous if

stored in leaden tanks. But there is now sold a magnetic, spongy carbon, which will remove both the dissolved lead and the peaty matter also. It has been found that the peaty waters brought from the distant moorland reservoirs to such places as Bradford dissolved much of the lead out of the surfaces of the leaden pipes by which they were conveyed to the consumers.—*Dr. Taylor in "Australasian."*

THE CLOSE OF THE CHINA TEA SEASON 1888-89.

The following figures are given in the *China Mail* of May 9th:—

TEA.—The market is closed for the season. Export of tea from all China:—

	Black. lb.	Green. lb.	Total. lb.
Season 1888-89.			
To Great Britain.....	96,806,256	5,956,399	102,762,655
To United States from China and Japan...	—	—	81,598,686
1887-88.			
To Great Britain...	115,196,768	8,083,542	123,280,310
To United States from China and Japan...	—	—	86,793,823
1886-87.			
To Great Britain...	143,761,872	7,405,797	151,167,669
To United States from China and Japan...	—	—	88,435,972

THE CHINA NEW TEA SEASON.

The first steamer to load new teas from Hankow was to leave Shanghai yesterday. We append list of the steamers that will probably load from that port:—

For London.	Tons Reg.	Horse Power.	Cargo Capacity. Tons.
"Moyune" ...	1,714	750	4,000
"Orestes" ...	1,321	300	3,200
"Sarpedon" ...	1,692	250	3,200
"Glamorganshire"	1,843	450	4,500
"Benledi" ...	1,498	350	3,700
"Aberdeen" ...	2,371	400	6,000
For Odessa	Tons Reg.	Horse Power.	Cargo Capacity. Tons.
"Glenartney" ...	1,400	320	3,200
"Mogul" ...	1,827	400	4,750
"Kostroma" ...	2,291	600	5,500
"Russian" ...	1,569	300	3,200
"Petersburg" ...	1,157	130	1,875
"Moskwa" ...	2,244	500	3,400

—*Shanghai Courier.* [A total of about 47,000 tons which is equal, we suppose, to about 50 million lb. of tea! But nearly half of this is for Russia direct: when shall we see a steamer loading at Colombo for Odessa?—*Ed.*]

PROGRESS IN PERAK: MINING AND PLANTING.

(From the *Perak Government Gazette.*)

MINING LANDS.

There are about 900 applicants for mining land still on the register. The majority of the applications are for land in Ulu Kinta. During the year 217 new mines, representing 2,500 acres were opened, and operations commenced. The number that ceased work from want of sufficient capital, unproductiveness of the ground, or other causes was 12. The figures speak well for the district as a mining centre. Correct returns of the export of tin are forwarded to the Treasurer, but it may be stated here that the out-put for 1888 was about 16,000 pikuls, giving an increase of about 3,000 pikuls over 1887. Comparing the years 1887-8, there is a decrease in the out-put from Japan, Kuala Tehja, and increases in the out-put from Sungie Raya, Ulu Kinta, Sungie Trap, and Kampar. The total

area alienated for mining purposes on 31st December, 1888, was 8,000 acres. The average mine is about 25 acres in extent, and is generally worked by small kongsis, assisted by advancers. There are two European companies at work in the district—viz., the Société des Etanis de Kinta and the Malayan Tin Mining Company. The Malayan Tin Mining Company first commenced operations at the close of the year at Seliebin, in Ulu Kinta. The Inspector of Machinery reports that there are 42 engines employed in the mines, and that they are on the increase.

ANCESTRAL MINES.

It is estimated that there are about 400 ancestral mines in Kinta. About one-third of the number have never been visited by European Officers. The greater number of them are situated in Ulu Kinta and Kampar. They are found also at various heights, almost inaccessible on the hills at Sungei Raya and other places. An effort will be made to get them all on to the register, but progress will be slow. The information Government would obtain in reference to mines in out-of-the-way places would scarcely compensate for the time, expense, and trouble of European Officers in reaching them. Separate reports have, at different times, been sent into Government regarding the ancestral mines at Kampa.

AGRICULTURAL LAND.

In a populous district like Kinta, with an estimated area of over 600 square miles, and a Malay population of about 12,000, and only 3,700 on the roll of agricultural holdings, it is obvious that a very large area of lands is occupied without any title. From the records of the Land Office, it would appear that about 9,000 acres of cultivated land are so occupied at the present time, but there can be little doubt that a thorough inspection will bring to light a large number of persons occupying land without any title whatever, all of whom should be registered holder and permanent contributors to the revenue. Every effort will be made to discover the delinquents, and bring them on to the roll, to which a large addition may be expected in the course of the current year.

SUPERINTENDENT GOVERNMENT PLANTATIONS ANNUAL REPORT, 1888.

For sake of comparison, I give expenditure back to 1885, though I did not think it necessary to put it into my report.

Expenditure 1889 (estimated)	\$7,850-00
" 1888 (actual)	11,398 01
" 1887 "	12,409 98
" 1886 "	12,692 02
" 1885 "	9,909 07

The year ending 31st December, 1888, has been marked by considerable progress in the development of planting in the State.

New clearings on Waterloo, leased by Sir Graeme Elphinstone, Bart., and Mr. Lutyens; the large new clearing on Kamuning, the property of Messrs. Hill and Rathborne! the tobacco experiment at Trong, conducted by same firm, combined with the cultivation of existing fields on Gula sugar estate of the Pe Sugar Cultivation Company, and Waterloo Estate mentioned before, go to prove that confidence in Perak as a legitimate field for planting enterprise is becoming firmly established on a sure basis.

Take Waterloo to begin with: In September, 1884, a mass ofalang and other pernicious weeds from top to bottom, by the end of the year, with the help of a favourably dry season, was comparatively clean. In Ceylon, no planter would have dreamt of weeding up this estate without at the same time rooting up the coffee with the view of planting tea. In this instance the coffee trees were no sooner free of weeds than they put forth their strength, so that—

In season 1885-6	a crop of parchment bushels..	1,037
Do 1886-7	do do do ...	1,976
Do 1887-8	do do do ...	906
Do 1888-9	do do do say over	2,000

In four seasons a total of bushels... 5,919

The acreage, by plan, off which those crops were picked is 70 acres 1 rood 35 poles. Allowing for ditch of

coffee trees and weeds, &c., the Manager, Mr. Thomas Fraser, deducts 25 per cent from total area, leaving 53 acres in coffee. This allowance is not over the mark, as Sir Graeme Elphinstone estimates the vacancies alone in certain fields at 40 per cent. Take, then, 5,919 bushels parchment coffee as the yield of 53 acres for four seasons. This gives an average of 1,480 bushels coffee for one season, equal to more than 5½ cwts, per acre per season. Be it noted that present season's crop is best of all, and is equal to 7½ cwts. per acre, this off coffee which in Ceylon, if subjected to same rough treatment, would have been one mass of leaf disease and dead sticks.

The actual acreage of this promising estate is—

	Acre.	Roods.	Poles.
Old coffee	70	1	35
New clearing planted ...	53	0	3
Ready for planting 1889	102	2	2
Total area...	226	0	0

With prices for coffee at present high rates it does not require much calculation to prove that the old coffee is a remunerative investment, will materially aid in opening up and bringing new clearings into bearing, and, what is of very great importance to the country, encourage the lessees to go on and others to follow their example.

* * * *

KAMUNING ESTATE.

The land for this estate has been carefully selected. The average soil of this country is naturally fertile: a fine deep loam, with limestone to quicken it, the soil becomes perfect for coffee. Kamuning is easy of access; in fact, it is a large tract of fine land unbroken by native claims, with Government cart road running through it right to the present railway terminus, a distance of 35 miles.

It is difficult to imagine a place starting under more favourable auspices. Under the management of Mr. Charles Wight, the undertaking will prove a credit to the country, and profitable to the fortunate proprietors.

The manager divides the clearing into four fields—

Number 1 containing	acres	80
Do 2 do	do	60
Do 3 do	do	70
Do 4 do	do	30

Total acres...240

Of this 160 acres were planted with Liberian coffee in N.E. monsoon

12 acres were planted with Pepper coffee in N. E. monsoon.

172 acres planted.

68 „ ready for planting.

Total 240 acres,

It is proposed to plant 30 acres of this clearing with pepper, the balance with Liberian coffee, interspersed with durian trees. One had to see the luxuriant growth of plants in the nursery only to augur most favourably of their future in the field. Everything has been done that planting experience and the ingenuity of man can devise to give the plants a fair start. The abundant rainfall on Kamuning is an element towards success, which must not be overlooked. Even sun-loving plants like Liberian coffee and pepper might have too much of the tropical sun pouring its fierce rays down on a black soil, rich in lime, were it not for the refreshing rains which fall frequently and freely, cooling and enriching the soil, and reanimating scorched vegetation. I very much regret I had no opportunity of visiting either Gula or Trong Estates, to say nothing of experimental gardens, chiefly in pepper, undertaken by Government in different localities.

* * * *

GOVERNMENT PLANTATIONS.

The commencement of tea manufacture was the most important feature of the year's work. We began making tea 14th February, and by the end of year had made 3,118 lb. against a revised estimate of 3,000 lb. Every one interested—His Excellency the Governor, the Hon. the Acting Colonial Secretary, the Hon. the

Acting Resident Councillor, Penang, &c., has had an opportunity of trying the tea. Samples have been sent to London and Ceylon, and have been favourably reported on. Every effort has been made to encourage local sale by advertising in *Gazette* and Singapore papers, by establishing agents in Singapore and Penang, and by distribution of samples, with poor results. This, though to be deplored, is not much to be wondered at, as Ceylon tea has deservedly a firm hold of the market, a position from which it would be difficult to oust it. The object Government had in view in planting tea has been attained; now what Government has to do is to make it widely known. The best way of accomplishing this is to put Perak tea on the lists in "the lane" along with tea from other countries.

Coffee most disappointing last year, nor, though in good condition and wonderfully free from leaf disease, does it promise to give a good yield this year. The soil is good; even on the top of the mountain, where trig station is, there is over eight feet of marvellously fine soil; the seasons and climate are suitable for coffee, the trees are well-planted, in good holes, and well-grown. The situation is against coffee. Coffee likes to nestle in the bosom of a mountain, with forest-clad summits towering above it. Coffee land should be drained from the very first to prevent wash, and save the precious salts deposited in the burning off of the forest. Coffee, more especially in steep land, should be kept free of weeds, to avoid disturbance of the soil in their removal. Though the yield of coffee leaves much to be desired, the quality is excellent, witness the sale in "the lane," 18th May 1887, of 41 bags, 1 packet averaging 101s 6d per cwt. The parcel sold last year was small, and failed to command the attention of the market.

The cattle on Government Plantations are very fine, the herd containing as it does the best strains of Alderney, Nellore, and Madras blood. The grassfields, when complete, will be of the greatest use and importance in affording suitable pasture for the herd, and enabling us to go on with breeding and cross-breeding, thereby raising the standard of the cattle of the country, which is at present very low. Much money is spent by proprietors at home with this object, where the necessity is not so great as here and surely the Government of this country stands as proprietor of the country and guardian of the people. * * *

The health of coolies in Government Plantations throughout the year has been excellent. Percentage of death, 1.49. Average number of sick coolies per day, .018.

Pepper cultivation promises to become a favourite and remunerative enterprise amongst natives and others in the country, and is worthy of every encouragement.

The small experimental garden at Gunong Pondok has been a school of instruction to Malays, who take a great interest in the work carried on there, and I look forward to having small gardens, varying from 2 to 30 acres, on both sides of the cart-road from Gapis to Kwala Kangsa. As industry increases, wealth grows, and with it population. It will take an effort to stir the Malays from their present lazy contentment, to make them ambitious, and give them a desire for wealth, but there are indications that the spirit which inspired them to invade this country is not dead, but may be roused to peaceful industry and useful arts. Chinese have been making enquiries of me about land for pepper and Liberian coffee. The Hindoo, at present centred in the towns, if properly led and looked after, will carry his tom-tom, his wife and family, with their interminable bickering and quarrels, into the country, and till the soil, as his ancestors have done for countless ages in India, in land more favoured by nature than the parched plains of his native country.—I have, &c.,

JOHN F. M. COCK, Jun.,
Superintendent, Government Plantations.

NOTES.

Mr. H. MULLINGHAUS, Manager of the Straits Trading Company, Limited, has opened a branch house in

the Kinta District, with the object of purchasing tin ore, to be smelted by scientific methods in Singapore. The objection to establishing a smelting factory in the State appears to be the enhanced cost of the coal, which would have to be shipped over from Penang or Singapore.

Applications from Europeans for mining concessions in the Bating Padang District are numerous.

Mr. A. A. SWAN is pushing on the survey of the proposed Teluk Anson-Tapa Railway. Plans for the section from Teluk Anson to Changkat Jong are expected to be ready by the end of May, and for that from Changkat Jong to Tapa by September.

The State Engineer has been recently engaged in the preliminary investigations for a trace from the Plus Valley towards Kelantan.

EASTERN PRODUCE AND ESTATES COMPANY, LIMITED.

(From the *Money Market Review*, April 27th, 1889.)

The second ordinary general meeting of shareholders was held on Thursday at the offices of the company, 27, Clement's-lane; Mr. C. J. LINDSAY NICHOLSON in the chair.

The notice calling the meeting was read by Mr. DOUGLAS R. SMITH (the secretary).

The report and accounts were taken as read.

The CHAIRMAN said: Gentlemen, I think it is my duty, in the first place, to express the pleasure that the directors have in meeting the shareholders of the reconstituted company today at the first annual meeting, and then briefly to go through the balance-sheet and the profit and loss account. If you will kindly turn to the balance-sheet you will find on the liability side that we have a capital in hand of £299,388; we have debentures £195,200 at 6 per cent.; we then have at the debit of estates reserve account, realisations, and recoveries the amount of £4,904 14s 2d, which is made up of the realisation of produce at a value over and above that fixed upon by the liquidators, and the proceeds of the sale of one estate. We have sundry creditors £7,738 9s 8d, bills payable £19,512 10s, and a balance of profit and loss account £465 13s 5d. On the asset or credit side we have an amount representing landed and other property acquired at Jan. 1st, 1888, under agreement dated Oct. 10th, 1887, of £436,117 4s. We have laid out on tea extensions £11,615 6s 10d; we have laid out on machinery and buildings £3,834, and from this we have written off for depreciation an amount of £1,051 17s 6d leaving that latter item now at £2,782 15s 6d. On the 30th December we had on hand £16,981 12s 7d of produce; but I may say that that amount has been almost realised since. Then we have advances against produce and supplies of estates, £9,156 2s; furniture, £111 19s 6d; sundry debtors, £21,788 9s 7d; bills receivable £967 12s 8d; and cash on deposit and at bankers, £31,019 15s 8d. Now, turning to the profit and loss account, you will see we have spent on upkeep of estates, including cost of purchased tea leaf and allowance for depreciation on machinery and buildings, £46,323 11s. The salaries, office expenses, and general charges in London and Ceylon have been £6,060 17s 6d, and the interest on our six per cent debentures amounted to £11,712. On the other side of the profit and loss account the proceeds of produce sold and brought to account at Dec. 31st and profits from agency business and interest, &c., amounted to £41,480 9s 4d, and we have the estimated value of produce on hand at December 31st last, £16,981 12s 7d. Your directors while they call this the second ordinary general meeting, would also call attention to the fact that these accounts only represent nine or ten months that the directors of this new company have been in touch with Ceylon; and when they say they pleased with the results, they based it upon the opinion that at the time this company was reconstituted you will remember it was stated it might be possible to go to the debenture holders, or some of them, for certain indulgence, in case we had to meet the preference dividend. I am glad to say the result of the year enabled us to meet every claim and pay

off the debenture interest, and also the interest upon the preference shares. (Hear, hear.) The result of the year's working had been injured, in a way, by the decadence of coffee in Ceylon. There seems no doubt that coffee appears to be going entirely out of Ceylon, and it seems to us only a question of time that coffee will cease to be a product of Ceylon. Consequently, we have substituted tea for the decaying coffee, and it has, in a measure, injured our results. We do not like to hazard an opinion, but if we can attach any weight to the reports which reach us since our report was made up, the coffee this year seems likely to repay the loss of last year and leave a profit. It is the blossom we depend upon; but Ceylon people know the disappointments which have arisen from time to time, and we do not attach too much importance to it. You will see that the yield of tea, 1888, from the company's estates was 986,800 lb., and the directors have thought it best to draw attention to the average gross price obtained, which was 1s per lb. for this company, which compares favourably with the average market price of 11³/₄d per lb. The directors feel that the real backbone of this concern is to be tea, and they are also of opinion that the quality of the tea produced will be the great feature if it is to be a feature at all. (Hear, hear.) Whilst on this subject I may read some remarks made by a great authority, namely, the Chancellor of the Exchequer, on the subject of Indian and Ceylon teas.

That is the opinion of a great authority. Our simple and private opinion is that we must endeavour to put upon the London market the best tea, our experience being that wherever low grade tea is sent prices are unremunerative for good and bad together. Indeed we believe that individual producers no less than the whole industry will gain by a high standard of quality. I do not know that there is anything more I need allude to, but will now move the adoption of the report and accounts, and then sit down and wait for any remarks which any gentleman may wish to make. I move that the report and accounts be received and adopted, and that a dividend of 5 per cent, per annum to the 31st December on the paid-up capital be declared on the preferred shares, payable on an after 30th inst.

Mr. DAVID REID seconded the motion, and said he believed the company had some very valuable property. There was no doubt, as the chairman had said, that tea was the backbone of the company, and the shareholders had reason to look forward with considerable hope to the working of the estate. They had some very able and experienced men on the estates, and a manager who had had a long experience of the working of estates in Ceylon. He believed the directors might look forward to meeting the shareholders in future years with improved balance-sheets. (Hear, hear.) As regards coffee, the prospects were, as regarded the blossom (as the chairman had said) good, but it was not always that they brought fruit.

A SHAREHOLDER referred to the "advances" on the credit side, and asked the nature of these. He referred to the subject because the old company got into some of its difficulties by making too many advances. Referring to the cash on deposit and at bankers, he said it seemed a large amount to keep at the bankers.

The CHAIRMAN said that, as regarded the advances against produce, &c., a part of the amount was to outsiders. Where the advances could be made prudently and well the directors thought it advisable to make such advances. As to the amount of money in hand and on deposit no doubt it was somewhat large, but it was mostly bringing in 4 per cent interest. On the other side of the accounts there was £5,615 to go for interest on debentures due on the 31st. As to the production of other articles besides tea and coffee, to which reference had been made, the company were continuing the cultivation of other articles, such as cinchona and cardamoms, and they were also making preparations to grow pepper; but the directors did not think that the matter was sufficiently important to allude to in the report.

The resolution for the adoption of the report and accounts was then put and carried.

Mr. L. MALCOLM said that under the articles of association all the directors retired *en bloc*; but he judged from the unanimity of the shareholders in the room that it was far from their wish that there should be any change. (Hear, hear.) Therefore, he had pleasure in proposing the re-election of the whole of the directors.

Mr. G. G. ANDERSON seconded the motion.

Mr. ATTLEE (solicitor) said it might, perhaps, seem an extraordinary thing that all the directors should retire; but when the company was formed the directors wished particularly that they should be submitted to the suffrages of the whole body of shareholders. It was pleasant to him, as solicitor to the company, to find so much unanimity in the meeting today. (Hear, hear.)

The resolution was then put and carried.

Mr. ROBERTS moved the re-election of the auditors, Messrs. Welton, Jones, and Co., with a remuneration of £50.

Mr. RUSSELL seconded the motion which was carried.

A cordial vote of thanks was then passed to the chairman, directors, and managing director.

The CHAIRMAN acknowledged the compliment.

The proceedings then terminated.

A FLAW IN BRITISH AGRICULTURE.

The *Scots Observer* says:—If a grazier is taken into a grass field, and asked what grasses are there it will very often be found that he cannot tell one grass from another: indeed, if you venture to say that such can be done by examining the species, he will probably assume that something is wrong with your brain. Still more, if a farmer is laying down land to grass, he fixes the quantity of each kind of seed neither by rhyme nor reason; he has a special liking for this or that grass, and he mixes in an extra quantity of peculiar seed. It is a fact, indeed, that forage cultivation is one of the most important branches of agriculture in Britain, and that our ignorance concerning it is so great as to be quite ruinous. The most favourable time for remedying this state of matters is the present: knowledge, if it does not come now, will come too late. It is time that our agricultural societies and the Government put their hands to the plough, and took ways and means to give sound instruction on all points connected with what is really a matter of national importance. For with her farmers skilled in grass production and stock-rearing Britain might defy the competition of the world.

“OOLONGS” vs. “CEYLON BREAKFAST” TEA FOR THE AMERICAN MARKET.

Pressure on our space forbids our entering on the discussion of this question beyond calling attention to two letters among our correspondence today. There is a good deal of truth in what “Ex-Canadian Resident” says about the people in the Western portion of the States and Canadian Dominion being far readier to accept a new article of consumption than in the Eastern States. And therein lies our justification for offering a certain degree of opposition to Mr. Francis Street, who, in a letter to a contemporary, apparently advocates that only “Oolongs” should be manufactured in Ceylon for the American market. This is going too far in our opinion. We expect to see the vast bulk of the American people—the coffee-drinkers especially—gradually brought to appreciate the full value of Ceylon tea as a refreshing beverage. “English breakfast tea”—a fair quality of China black tea—we found in 1884 provided at all hotels from San Francisco to Boston, and from Toronto to

Florida, and many Americans now regularly drink such tea, though, of course, the larger number still prefer green teas. We would have Ceylon planters study the wants of both. A certain proportion of Oolongs may well be locally made; but certainly the bulk of the tea with which Ceylon is to storm the American market must be of the superior black description which is already so much appreciated all over Britain. Throughout Canada, and in the Middle and Western States, there ought to be no difficulty in finding a market for such teas and in securing a rapidly increasing appreciation of them. The case is different, we admit, in New York, New England and the populous East Coast States generally; and therefore there is a good deal of reason at this time of depression why not a few of our planters should endeavour to follow the example of Mr. Shand of Rakwana in manufacturing a certain proportion of Oolongs. Mr. Street has been buying a small lot, 1½ chest of Oolong Pekoe at the last Colombo sales, at 60 cents, with which he is well satisfied, and he is evidently prepared to do business to a considerable extent, while he testifies that from more than one quarter, in the hill-country as well as Rakwana, he has had samples of superior Oolongs showing that Ceylon planters can well compete with the China makers of green teas in the American market. This is very encouraging at a time when every resource must be availed of to relieve the pressure on our tea making, and we shall at once look up the plainest instructions available in respect of the making of “Oolongs” for the benefit of those who wish to follow the Rakwana example. But, nevertheless, we trust that the bulk of the tea to be introduced into America from Ceylon may be of our Pekoes and Pekoe Souchongs and that the demand for these will go on steadily increasing until the taste for Oolongs whether of pure manufacture, or artificially faced—as the vast bulk of the Japan if not China green teas is,—is finally eradicated.

CINCHONA CULTIVATION IN JAVA: GOVERNMENT vs. PLANTERS.

We have received in the form of a pamphlet, reprinted from the Batavia *Tijdschrift van Nijverheid en Landbouw* for May, the minutes of proceedings at a general meeting of the Soekaboemi Agricultural Association held on 14th Jan. The subject that evoked most discussion was cinchona. The Association had received from the Nederland branch of the Netherlands India Company of Industry and Agriculture a note to H. E. the Minister for the Colonies respecting the petition of certain persons interested in cinchona cultivation in Netherlands India to the Governor there, asking that the Government cinchona culture in Java should be no further extended but on the contrary restricted and gradually abandoned. The President (Mr. G. Mundt) having called upon Mr. Massink, a member of the Association, that gentleman made a lengthy speech. He said that on receipt of a similar note the Bandoeng Agricultural Association had resolved to refuse their adhesion thereto. The Association referred to had come to this conclusion in consequence of the explanations given them by their President, who was also Director of the Government Cinchona Enterprise. Mr. Massink wished however to add, that the Director of the Government Cinchona Enterprise had handled the note of the Nederland branch as gingerly as a cat would treat hot porridge. On the minor points he was very discursive, but the chief questions he left undealt with. The question however was twofold, and it included (1)

restriction of the Government gardens, and (2) establishment of an experimental station. With regard to the first point, Mr. Massink stated that he had failed to discover any arguments against it, and he quoted figures showing the harm done to private enterprise by the Government gardens, which could throw yearly 3,600,000 half-kilograms of bark or 252,000 half-kilograms of sulphate of quinine on the market. The second point in the petition of the *Nederland* branch, said Mr. Massink, had also been left undealt with by the President-Director; and the request was one of even greater importance to the planters, in view of the diseases to which it was now known the cinchona trees were liable. He then made a comparison between the Government Cinchona Enterprise and the Botanical Garden at Buitenzorg, showing that while the former brought into the Government treasury a hundred thousand guilders net each year it did absolutely nothing for the benefit of the planters, but, on the contrary benefited at their expense; while the latter, though a source of loss to the Government, had been of the greatest help in many ways to the planting industry, which was the mainstay of Java: several instances being given. The President here remarked that he could not admit that the Director of the Cinchona Enterprise was not fully aware of the danger hanging over the cinchona market in consequence of the great outturn of the rich Government bark: to which Mr. Massink replied by reiterating that the Director had beat about the bush and shirked the main question. Another member, Mr. Burger, however, said that in his opinion the Director either was not or would not be aware of the danger referred to; and the President confessed that the large production of the Government gardens was undoubtedly a cause of injury to private planters, who were already so severely handicapped. A somewhat heated debate followed, in which an honorary member, Mr. van Vleuten, Director of the Inland Administration, defended the Director of the Government Cinchona Enterprise, the management of which he compared with that of private estates, to the disparagement of the latter. Messrs. Massink and Burger replied to his criticisms, and the subject seems then to have dropped without any resolution being come to. It is, however, significant, that a subsequent minute runs:—"Received with thanks from the Director of the Government Cinchona Enterprise, in *January 1889*, the Annual Report on the enterprise in question for 1887," the italicized word and figures being printed in the original in black type.

BARK AND DRUG TRADE REPORT.

LONDON, 2nd May 1889.

ANNATTO.—Some good bright red seeds from South America (shipped here *via* Hamburg) were offered today, and sold at 2d per lb. Dry Brazilian roll annatto was bought in at 1s per lb. Cayenne annatto is held at 1s to 1s 2d per lb in Liverpool.

CARDAMOMS.—Very heavy quantities were bought to auction this week, the total number of packages offered exceeding 400. Some of the owners, especially those holding Indian cardamoms, were limited above the present market values, and withdrew the whole of their supply, but others offered freely, and of the 243 packages reached today, about 150 were sold at an irregular decline of from 2d to 5d per lb, medium qualities being comparatively dearest. The following prices were paid:—Ceylon Malabar, fair round brownish mixed, rather light 1s 8d to 1s 10d; smaller but paler 1s 6d to 1s 8d; small pale round 1s 6d; ordinary brown small to medium specky 1s to 1s 1d; split shells and clippings 6d per lb. Mysore, fine pale medium to bold long and round mixed 2s 9d to 2s 11d; fair medium long brown-

ish, mixed 1s 10d; small pale round 1s 9d; small to medium long and round pale heavy 1s 7d to 1s 8d; small to medium fair pale 1s 3d to 1s 5d; small to medium brown 1s 1d; good small long, very pale bleached 1s; small pale 9d to 10½d; ordinary brown and specky 8d per lb. True Malabar, even, pale medium round 1s 11d; very small to medium round 1s to 1s 7d. Wild Ceylon, fair to fine 1s 3d to 1s 7d. Seed 1s 3d to 1s 4d per lb. The shipments from Ceylon have fallen off lately. They now total up as follows for the periods between October 1st and April 4th:—1888-89, 183,016 lb; 1887-88, 212,066 lb; 1886-87, 204,983 lb.

CINCHONA.—At today's auctions two packages South American red bark of dull colour were sold at the very high price of 8s per lb for fair to heavy broken quill and flat, and 2s for ordinary thin mixed broken quill. Guayaquil long brown quill, partly damaged brought 6d to 9d per lb. For Huanoco brown quill 11d was refused. For good bright broken Lima quill 2½d per lb was refused one lot; flat yellow Calisaya sold at 1s 8d per lb, a large quantity was bought in. Maracaibo firmly held for full rates. A parcel imported *via* Hamburg sold at 7d to 7½d for the damages, but 8d was refused for sound lots. At present about 2,400 packages (about one-half of British Indian growth) are advertised for sale next Tuesday. The exports of cinchona bark from Java in the eight months between July 1st and February 28th have been as follows:—

	1888-9	1887-8	1886-7	1885-6
	Amst. lb.	Amst. lb.	Amst. lb.	Amst. lb.
Private plant.	2,444,870	2,001,171	1,125,310	677,627
Government plant.	529,110	490,653	480,777	330,242
Total	2,973,980	2,491,824	1,606,087	1,007,869

CLOVES have been in speculative request since last week, and a considerable advance has been made; but at yesterday's auctions the article was again at ¼d lower, at 7½d to 7¾d for fair to good, and 8½d for fine Zanzibar.

COCA LEAVES.—Tomorrow a few bales of fine quality will be offered, including leaves grown in Ceylon and in Java.

CROTON-SEED.—Only 10 bags brown mixed Ceylon seed were shown today, and sold at the low price of 11s per cwt.

OIL (ESSENTIAL).—Some cinnamon "bark" oil sold very cheaply at 1½d per oz., but for a good oil of cinnamon 1s 3d per oz. is wanted. The exports of cinnamon bark and leaf oil from Ceylon are considerably less this season than they have been for several years, the figures being between October 1st and April 4th; 1888-89 26,187 oz.; 1887-88 46,292 oz.; 1886-87, 43,447 oz. Citronella oil is dull at ¾d to ¾d per oz. for native brands. The following figures refer to the shipments of citronella oil from Ceylon during the periods between October 1st and April 4th; 1888-89, 7,660,660 oz.; 1887-88, 4,870,162 oz.; 1886-87, 3,951,264 oz.

PATCHOULY LEAVES.—A second bale of West Indian leaves arrived this week. In appearance this variety shows a very fine green leaf of very pronounced aroma. At the auctions brown and stalky leaves imported *via* Singapore were offered at 4½d per oz.

QUININE lower. There has been very little doing since our last report but during the latter part of this week German in bulk has declined to 1s 1d and 1s 0½d per oz., at both of which figures business is said to have been done.

THE AMSTERDAM CINCHONA AUCTIONS.

AMSTERDAM, May 2nd.—At today's cinchona auctions 2,339 packages, nearly all Java bark, were offered for sale. Of this quantity, 1,964 packages were disposed of at an average unit price of 8 to 9 cents per ½ kilo. (= 1½d to 1 9-16d per lb.) Manufacturers' bark sold at 11 to 82 cents per ½ kilo. (= 2d to 1s 2½d per lb.) for quill, broken quill, and chips, and 13 to 19 cents (= 2½d to 3½d) for root. Druggists' barks, in long to broken quill and branch, sold at 6 to 6½ cents (= 1d to 1½d per lb.), and root bark at 6 to 59 cents (= 1d to 10½d per lb.) The principal

buyers were the Auerbach Quinine Factory, the Amsterdam Quinine-works, and Messrs. Zimmer & Co., of Frankfort-on-the-Main.—*Chemist and Druggist*.

MANDIOCA IN BRAZIL.

A curious and somewhat anomalous complication has arisen in Pernambuco over an effort of the president of that province to restrict and control the trade in mandioca flour (*farinha*). The drouth in Ceará has created an extraordinary demand for this article, and as many of the poor people there are in a famishing condition it must be had at any cost. Pernambuco being the nearest port where a considerable supply can be obtained, the shipments from that province have largely increased and the price has consequently rapidly advanced. This in turn has created much discontent among the poorer classes in Pernambuco and the charges that the *farinha* trade has fallen into the hands of speculators and monopolists has created a strong popular feeling against them. This sentiment culminated about the middle of last week in popular meetings to protest against the monopoly, and then in an order from the president prohibiting the exportation of the article. The Commercial Association promptly protested against this arbitrary interference with commerce and petitioned the imperial government for relief, but to no effect. Aside from the suspension of an important branch of inter-provincial trade, the order vitiates contracts and freight charters and inflicts much unnecessary loss upon merchants and shippers. We are informed that the president has ample authority for the step taken; in which case it is an authority that ought to be revoked at once. The power to suspend any branch of legitimate trade, especially between neighboring provinces, is eminently dangerous, and especially so in the hands of unscrupulous men. If the telegrams of the 30th are true—in which it is stated that the president of Pernambuco is buying *farinha* for account of the president of Ceará—then no further proof is needed as to the irregular and scandalous character of the whole proceeding. We are not in sympathy with the speculators who may be seeking to coin money from the starving refugees of Ceará, nor with the monopolists who combine to elevate prices in Pernambuco; but surely there is some better and safer way to meet the emergency than through the exercise of autocratic power by an irresponsible provincial president!—*Rio News*, April 1st.

CORALS.—Professor Dana has recently reviewed the so-called new evidence of Dr. Murray, Dr. Guppy, and others, which seemed to militate against Darwin's original theory of oceanic islands and coral reefs. Dr. Dana took the Hawaiian Islands as examples, and showed that they really are extinct volcanoes in different states of degradation. He concludes that neither Murray nor Guppy have brought forward any serious facts to disprove Darwin's original theory, or even to set aside the facts in its favour.—*Australasian*.

COFFEE LEAF DISEASE.—Dr. Burck, Director of the Government Botanical Garden there, has delivered a lecture on the coffee leaf disease, which has wrought such havoc in Java. The lecturer, who has made the subject a special study, recommended, as an effective remedy against the plague, the sprinkling of young coffee plants in the nurseries with tobacco water. In his opinion high fences of trees around coffee estates would keep off winds laden with disease germs. Cutting out plague spots from stricken trees and injecting a certain chemical solution into diseased leaves find favour with him.—*Straits Times*, 15th May.

THE TEA MERCHANTS of Kyoto, Osaka, Shigaken and Mie-ken intend to establish a tea inspection department at Kobe. To maintain this it is estimated will entail \$4,000 yearly, which sum is to be raised by the imposition of a charge of 3½ or 4 cents per package on the 150,000 packages of tea annually exported from Kobe.—*Japan paper*.

EGYPTIAN COTTON.—Two kinds of cotton are grown in Mysore, the Chic Uthee or indigenous variety, and the Dod Er-hee or Egyptian variety. The staple of the latter is longer and stronger than the common variety and the shrub is much hardier, requiring less water. We hear that the Durbar is about to offer certain prizes for the encouragement of the planting of the Egyptian variety.—*Bangalore Spectator*.

THE AMSTERDAM QUININE WORKS.—The annual meeting of shareholders in the above-named works was held in Amsterdam on Monday, April 29th, when a dividend for the year 1888 of 29f. per share of 500f. (or 5.4-5th per cent.) was declared. It was stated that during the year under view the works had turned out over 350,000 oz. of sulphate of quinine, which had found a satisfactory market, although the average profit had, of course, been but a small one. Permission was given to the board of directors to issue the remaining 100 shares (of 500f. each) for the purpose of taking up the manufacture of other chemical products in addition to quinine salts.—*Chemist and Druggist*.

ADULTERATED TEA OF REPORTED ENGLISH ORIGIN.—Some time since the Dunquerque municipal laboratory seized in a local shop specimens of tea which proved to be adulterated. The cases had been procured from a Paris house, where samples were also seized, and submitted to Professor Riche, of the College of Pharmacy, and another professor of the same institution. They have found the leaves to be naturally brown, but to have been dyed bluish green and rolled up so as to resemble the sort known as gunpowder tea. A strange circumstance is that the specimens were found to contain small quantities of theine. The leaves, apparently from a shrub of the *Camelia* family, had been shorn so as to acquire the long ovoid form of genuine tea. But they are not tea leaves. A suspicious fact is the extreme cheapness of the price at which they were offered. The Paris firm admitted they had imported the goods in question, but denied having adulterated them in any way. They declared they procured them as they were direct from an English house at Canton, whose name has not transpired. It is likely something more will be heard about the affair.—*Chemist and Druggist*, April 27th.

FISH CULTURE.—“An acre of water is worth two acres of land, and frequently much more.” Such is the startling statement made in the *The Times* by that experienced pisciculturist Mr. William Burgess, of Malvern Wells. Mr. Burgess maintains, and he is in a position to know, that “the old system of breeding fish in ponds might be profitably revived, and that every piece of water, whether it be pond, lake, or stream, ought to be cultivated by its owner in view of the commercial value of fish, whether for the purpose of local consumption or for increasing the live stock for sporting purposes.” And Mr. Burgess backs his precept with very handsome practice, for he offers, in order to assist public bodies in replenishing depleted waters, to “receive and hatch out free of charge any quantity of ova next season, returning the fry when liberated from the capsules to their respective owners.” It is to be hoped that this good seed will fall on fertile soil. Here is a chance surely for landowners whose property has been damaged by a surfeit of water, of plucking the flower. Safety from the nettle Danger, and of gathering a harvest which no vicissitudes of the seasons can affect.—*Indian Planters' Gazette*.

Correspondence.

To the Editor.

BLACK BUG IN COFFEE.

Pagilaran (Pekalongan), Java, 27th April 1889.

GENTLEMEN,—I trust you will excuse the liberty I take in thus addressing you, but having heard that one of the greatest enemies of the coffee-tree, viz., the *black bug*, has almost disappeared from Ceylon, you would very much oblige me by informing me, by what means that happy result is obtained? Begging you will kindly excuse the trouble I am giving you and thanking you beforehand for your information, I remain, gentlemen, your obedient servant,

J. EBELING.

[Mr. Ebeling may be confounding black with green bug; he should read Nietner's pamphlet on the former and Mr. Green's monograph on the latter. Black bug ceased to affect Ceylon coffee seriously nearly 35 years ago, disappearing gradually, although patches here and there in high districts may still be seen occasionally; but the modern trouble has been *green bug* following on the leaf fungus, and for this there is no specific (any more than for black bug).—Thatching the soil with grass around the stems of the coffee trees was one means of taking black bug off the coffee; while washing the stems with coarse soap and sprinkling with a mixture of kerosene oil and water has been tried with some effect for green bug.—Ed.]

COCA LEAVES : ENCOURAGEMENT TO CEYLON PLANTERS OF ERYTHROXYLON COCA.

London, E.C., 3rd May 1889.

DEAR SIR,—No doubt you have been informed that the coca leaves from Ceylon were considered very fine indeed, and were purchased at 1s 10d per lb.; they were like the old-fashioned Bolivian leaves.—Yours faithfully,

THOMAS CHRISTY & Co.

EGGS ALL IN ONE BASKET AGAIN!

DEAR SIR,—When coffee failed and brought disaster upon all involved in it, if one lesson above all others was taught, urged, insisted upon and repeated over and over again, that lesson was: "Never again let Ceylon planters put all their eggs into one basket!" And yet what have they now done? Is tea not worse overdone than ever coffee was? Some excuse may be urged for the unlucky coffee planters who found themselves with estates on their hands well roaded, lined, drained and provided with expensive buildings, the majority of them too steep and rugged for the cultivation of anything not permanently fixed in the soil. For their lands tea offered the most suitable substitute for the departed coffee, after cinchona got played out; and all would have been well had "tea" flourished only in the coffee zone. But inasmuch as it is a weed quite as fit and ready to be grown up the sides of Pidurutalagala as at the sea-level, and everywhere between, and in the patana lands abhorred by coffee, is there any wonder that six short years have sufficed to see it overdone? Are not all our eggs again in one basket?

The "Movements of Tea" to 31st March, however, do not seem in any way to warrant the present scare. An article by you, sir, on the "statistics" might do something to allay this, and bring it home to its true cause: the death-throes of cheap China congous. PLANTER.

[We are waiting for the news of the opening of the new tea season at the China ports, before venturing to discuss the position or prospects.—Ed.]

INDIAN TEA EXPORTS.

Indian Tea Association, Chamber of Commerce, Calcutta, 13th May 1889.

DEAR SIR,—The General Committee have the pleasure to hand you their usual monthly return of shipments of tea from Calcutta.

Exports of Indian Tea from Calcutta:—

	1889 lb	1888 lb	1887 lb
Exports to Great Britain in April ...	221,620	264,522	291,697
Exports to Great Britain from 1st May to 30th April ...	92,492,463	83,419,608	75,857,665
Exports to Australia and New Zealand in April ...	10,685	40	3,896
Exports to Australia and New Zealand from 1st May to 30th April ...	2,869,184	2,408,019	1,567,170
Exports to America in April ...	5,120	—	510
Exports to America from 1st May to 30th April ...	174,538	48,115	99,126
Exports to other places in April ...	166,806	21,000	71,696
Exports to other places from 1st May to 30th April ...	1,235,087	1,109,696	1,120,188
Total exports from 1st May to 30th April ...	96,771,272	86,935,438	78,644,14

—Yours faithfully, G. M. BARTON, Asst. Secy.

THE CONSUMPTION OF TEA IN GERMANY.

13, Rood Lane, London, 10th May 1889.

DEAR SIR,—In the Overland edition of the *Ceylon Observer* of the 10th April, you published a letter headed "Ceylon Teas and How to Push Them:—No. 2," signed by "A Citizen of the World."

In this letter the writer after making various remarks concerning the duty levied upon tea imported into France, which is correctly given in our circular, alludes to a diagram we published, showing the quantity of tea consumed in various countries.

Your correspondent confounds the amount of tea actually consumed in Germany with the quantity of tea shipped from Great Britain to Germany, the greater portion of which only passes through Germany to other places.

The two tables given in our circular, to which your correspondent refers, are totally distinct, and we believe an ordinary reader would see that no connection exists between them; as an instance we may state that in the diagram the *consumption* in the U. S. A. is given as 90 million lb., while the table shows that only 3,115,822 lb. were imported from England.

The following information may be interesting to your readers:—

	Tea consumed in Germany.	Tea exported from Great Britain into Germany (mostly for re-export.)
1881 ...	3,270,620	18,569,682
1882 ...	3,275,036	16,693,289
1883 ...	3,513,379	18,647,379
1884 ...	3,442,757	21,052,071
1885 ...	3,950,221	14,705,421
1886 ...	3,923,894	18,028,566
1887 (Returns not yet to hand)		8,617,648

—We are, dear sir, yours faithfully,
GOW, WILSON & STANTON.

FIRE EXTINGUISHERS.

DEAR SIR,—All proprietors of tea factories should make a note of the following:—

WHAT EVERY HOUSEKEEPER SHOULD DO

A physician has imparted to the "Atlanta Constitution," for domestic application the exact recipe for the solution used in the fire extinguishers now offered for sale, as follows:—"Take twenty pounds of common salt and ten pounds of sal ammoniac (muriate of ammonia, to be had of any druggist) and dissolve in seven gallons of water. When dissolved it can be bottled and

kept in each room in the house to be used in an emergency. In case of a fire occurring one or two bottles should immediately be thrown with force into the burning places so as to break them, and the fire will certainly be extinguished."

This may prove useful to proprietors of factories in Ceylon and be the means of preventing a fire or putting one out. TEA PLANTER.

TEA : FINE, MEDIUM AND COARSE PLUCKING.

Matale, 15th May 1889.

DEAR SIR,—Why not take up the subject of "What are we to understand by fine plucking, say from three to five months after pruning?" We hear a great deal about fine plucking, but opinions on this subject are so varied, that a synopsis of them would be useful. When the flush runs to four leaves and the bud above the fish leaf, as in many instances it often does when you want to pluck *only two and the bud*, which is considered medium plucking? Should the third leaf be plucked and thrown away? Or, if put amongst the leaf in the cooly's basket, would such leaf be called coarse? Medium plucking, as I understand it, is two leaves and the bud, plucked at the proper time, leaving only one developed leaf on the shoot. If this be so, what is fine plucking? Less than this I consider will not pay at the price of loss in leaf, and for the injury which finer plucking will do to the bushes.—Yours faithfully, JUNIOR.

THE CHINA TEA SEASON AND TEA PROSPECTS GENERALLY.

Colombo, 18th May 1889.

DEAR SIR,—I agree with you that there is not the least use in discussing tea statistics till it is seen what China is to do. I haven't the least doubt myself China will ship all the tea the trade now requires from her. The Hankow first crop promises to be a larger one than ever. The size of the second and third will of course depend upon the demand for it. If the teas are good—as I am inclined to think they will be—there will be no lack of buyers you will find.

Foochow buyers have gone out quite confident that they are going to make money this season, but I rather fancy their London constituents don't take the same view, judging by the orders given out; but I don't doubt the orders will be sent out by wire, when the quality of the crop and the scale of opening prices are known. The failure of two of the largest Foochow buyers (one the large "Auction Firm" of Geo. Oliver & Co.; the other a man who only started on his own account last season) will create more healthy business this coming season. I am told the losses on China tea in Australia last season have been the most serious for years past. Everything in Foochow points to a late opening at low prices, and in Hankow the reverse, as handsome profits were made on the early realized first crops. Hankow buyers are, I expect, in the thick of it by this time.—Yours truly,

OLD HAND.

TEA : RATES, PLUCKING AND PRICES.

SIR,—I annex table showing the different rates which tea must fetch per lb. at different yields in order to cover expenditure, calculated on an ordinary expenditure of R50 per acre general upkeep, as this will not vary whether fine or coarse plucking is carried out. The cost of plucking, manufacture, etc., is shown in another column at different rates for varying yields. From the figures it would seem to pay better to pluck

medium or coarse than fine, as 400 lb. per acre at 9d gives R50 per acre profit, whereas with 200 lb. per acre an average price of 1/1½ is required to get the same profit, which price is more than many broken pekoes are fetching at the present moment, while our average price has not yet dropped to 9d. For estates giving 500 lb. and upwards 8d per lb. and less will give R50 profit per acre, so there is still a margin for large yielding estates, but estates giving about 200 lb. unless getting above the average have very little to go upon and must be scarcely paying their way.—Yours truly, SABARAGAMUWA.

Table showing price required to give R50 profit per acre with varying yields, ordinary upkeep being R50 per acre :

Yield per acre.	At per lb.	Colombo equivalent.	Gross receipts per acre.		Ordinary upkeep		Cost of plucking, manufacture, packing, etc. to Colombo.		Nett profit per acre.	Cost of manufacture, plucking, packing & transport to Colombo taken at

TEA LEAD.

DEAR SIR.—A good deal has been written lately re tea boxes, but why has the question of tea lead been neglected? What matters it how suitable the boxes may be if the lead itself is defective? Now is the time to determine by discussion whether one is safe in using 4 ounce instead of 5 ounce lead. It is said that if you hold up to a strong light sheets of the former you can positively see through them! I can quite understand that 4 oz. lead if sound may do very well for small packets, but is it suitable lead for chests is the question. Is any lead heavier than 5 ounce ever used?

PROPRIETOR.

IN FAVOUR OF JAPANESE BOXES; COTTON CULTURE AND PREPARATION.

May 18th.

DEAR SIR,—In support of Japanese cedar boxes: I have used these for two years and never received a word of complaint either as regards brittleness or tainting the tea. I have always used the 5½ in. half-chests and ½ in. full chests. Lately I have been using estate-made boxes, but intend returning to the Japanese packages when my estate boxes are finished.

Re Cotton.—Intending growers should peruse a very useful summary of instructions given in your *T. A.*, March 1, 1883, page 733, issued by Natal Chamber of Commerce. The cultivation there lies in a nutshell. What we want now is a *brochure* on the preparation for the market.—Yours,
GIDEON.

THE TEA CRISIS:
QUESTIONS TO THE POINT.

DEAR SIR.—Perhaps "A Colombo Man" will answer some of the following questions, which bear upon the point he has raised of quality *v.* quantity.

- (1) Can some lowcountry districts produce teas of high quality such as now command prices in the London market?
- (2) If all the estates in Ceylon had by finer plucking in the last season produced, say $\frac{2}{3}$ of the crop actually secured, would this have averted a crisis in the future, or only postponed it?
- (3) Were all estates in Ceylon to produce tea of such fine quality as say Hoolankande would the market average now be 1s 10d?
- (4) If manufacture and plucking were uniformly even, would not some estates (from their superior advantages of soil, climate, or elevation) excel others in price of tea sold?
- (5) Are not inferior teas and dust at the present moment selling comparatively dearer than good, well-made pekoes and pekoe souchongs?
- (6) Have such estates as Blackstone and Loolcondra altered their system of plucking and manufacture? If so, was it done with the object of increasing or diminishing their profits? If not, are they culpable for the lower prices now paid for their teas? The real question at issue is "Which pays best, quantity or quality?" and how far either should be sacrificed to promote the other?—Yours truly,
SUPERINTENDENT.

CEYLON TEA TRADE IN NORTH AMERICA AND CANADA.

Ceylon, May 18th, 1889.

SIR,—Judging from the constant reference in your leading journal to the importance of opening special markets for the sale of Ceylon-grown teas, and particularly noticing the formation of a Planters' Company for the extension of business in this way in the United States of America through Mr. Pineo to work apparently from New York as a base of operations, I may be allowed to offer a few remarks on the subject, as one who knows America fairly well and Canada even better, and observe, that in my opinion the Planters' Company is foregoing an immense advantage which the geographical position of Ceylon gives it, in not taking this important work in hand from what I may call the rear, instead of the front of the trade, which I may term such bases as New York or Boston.

For although in this way you have the Suez Canal open and lines of established communication, more conveniently accessible—you strike old vested interests in New York and Boston more likely to be obstructive, where the most narrow-minded protectionists abound: and where a "ring" against you among dealers could easily be formed as unscrupulous as any 'Tammany ring' that was ever created.

My recommendation would be to start an agency for America in San Francisco and another at New Westminster in British Columbia, to tap the trade with Canada; these important points being only 750 geographical miles apart, and for the following reasons:—

1st. The Suez Canal may by war or some contingent stoppage be unavailable.

2ndly. During winter the climatic advantages of working from the British Columbia and San Francisco side are enormous, as compared with New York, Boston, or Halifax.

Canada by way of the St. Lawrence is practically closed for six months in the year, viz., from the middle of November when the last Allan liner leaves Quebec to the middle of May when their first mail boat arrives out; and granting that Halifax is open for the sake of the mails, the steamers even there often arrive covered with icicles, and New York and Boston, although better, still suffer somewhat during the winter months.

Then as above noted you encounter the most unscrupulous of protectionist bigots in those places, while on the western slopes of the Rocky Mountains as far north as British Columbia you have a temperate climate, an all the year round trade, and a population far more friendly in their ideas, while the harbour facilities in both San Francisco and New Westminster are unsurpassed, one of the largest graving docks capable of taking in a modern ironclad having only recently been completed by the Government at Esquimaux close to New Westminster.

The great centre of trade for Ceylon to get a foothold in, is undoubtedly Chicago, which is just as easily reached by rail from San Francisco as from New York. Its gigantic trade may be illustrated in the one item of grain alone, there being at least twenty grain elevators there, capable of storing 30,000,000 bushels of grain, representing by railway measurement in the season 14 train miles of covered wagons of grain every day. Once tap Chicago from the West, and gets depôts along the Chicago, Milwaukee, St. Paul, and Winnipeg railway now in the hands of the Grand Trunk, coupled also with the southward line of the Mississippi to St. Louis and Memphis, both cities now almost competing with Chicago, and I venture to say that an area of population would be reached which would contain the largest consumers possible of "the drink that cheers, but not inebriate," that can be found, and equal to the purchase of all the tea Ceylon could produce.

Again, along the line of the Canada Pacific Railway from its terminus at New Westminster all the trading stations of Manitoba and Winnipeg could be reached in all seasons of the year, well-known to be a tea-drinking community of almost entirely British settlers.

It occurs to me to suggest in conclusion, that an effort should be made to enclose the tea in handy parcels from $\frac{1}{2}$ lb. to 1, 2, and 3 lb. in the paper specially used for these purposes, almost impervious to damp and scentless, and covered with tinfoil if necessary, and packed again in larger cases as in ordinary chests. Buyers of these could at once establish small shops at the railway stations such as Cooper, Cooper & Co. and the United Kingdom Tea Company do at the railway stations in England, and a roaring and profitable trade might be done with a possible quarter of million to the shareholders "reserve fund" in a very few years.—Yours truly,
EX-CANADIAN RESIDENT.

CEYLON TEA IN AMERICA.

23rd May.

DEAR SIR,—I like the "ring" about "Ex-Canadian Resident's" letter. He seems to know clearly what he is writing about. A pity we had not funds sufficient to induce him to proceed to the attack in the quarters he suggests in addition to the Pineo scheme. Surely both could not fail, and if both were a success, what a splendid thing it would be for Ceylon. While Mr. Pineo is still amongst us, waiting simply for orders to slip his cables, perhaps he will notice the letter above referred to.

PROPRIETOR.

THE CEYLON-AMERICAN TEA COMPANY.

Castlereagh, Dikoya, 18th May 1889.

DEAR SIR,—I notice in your issue of the 17th a letter signed "Shareholder" offering suggestions re the Ceylon Planters' American Tea Company. He is perfectly right in saying that no time must be wasted; we cannot move too soon, but it must be remembered that we must first form the Company; this is what the Provisional Board of Directors are striving their utmost to do; the Company once floated, that is a sufficient number of shares taken to enable a start, of course a meeting of all interested will be called to appoint a Board. "Shareholder" though little knows the indifference shown in quarters where one would expect the greatest interest. With a market falling rapidly, it is amazing to hear a proprietor say: "I don't believe in putting money into other people's pockets." Another: "I want to see the price of tea fall, for not till then will we have a chance with China." While some object to the word Planters' Company; and others think the offices and directors should all be in Colombo. These are some of the reasons given for not subscribing.

This Company must be floated, and floated I am quite sure it will be. Call it by any name you like, have the offices in Colombo, and the whole Board Colombo men, by all means; only let us get under weigh. Till men come forward and take shares they are ineligible as directors. There are now about 1,100 shares taken. I would that every estate in the island took one share, and every superintendent one, and let our Colombo friends and the proprietors come forward and the 5,000 shares available for Ceylon would soon be taken up; there are many considerations to be taken into account and discussed, much that is open to criticism doubtless. All this is a matter for the shareholders; let them only join and then appoint their own Board to work the Company as the majority wish. That it is necessary that we try and get into the American market all will admit. The Tea Fund, while doing excellent work, cannot tackle so large an undertaking; the Elwood May Scheme fell through of necessity, and the present Company is put before the public. Not only is it to make our teas known in America, but by establishing agencies it is to push the sale of pure Ceylon tea bought in the open market in Colombo, which will be sold at fair rates not at fancy prices. That our teas will sell where known has been proved over and over again. When in Colombo last April I saw an order from Australia for 20,000 lb., the outcome of the Melbourne Exhibition entirely. Most of us know of the order from Persia, the result of one of our bankers sending some of our tea to the new agency there, and the result of the Tea Fund grant to Mr. Fenton Wingate on his late trip to New Zealand is a trial order of some 5,000 lb from the New Zealand Farmers' Co-operative Society of Canterbury; these are only a few instances. Again I say, start this Company we must, and I appeal to all to come forward and help. A meeting of the provisional directors is to be held in Kandy on the 24th to decide as to whether the Company is to be gone on with. I can only express the earnest hope that before that date, applications for shares will have come in from all sides so that the work of attacking the American market may be commenced at once. Well supported and well directed not only should the Company do incalculable good to the tea industry, but to the whole Colony generally, besides paying each shareholder an acceptable percentage. The meaning of preventing a fall of 2c per lb. on the 50,000,000 lb. we shall export in to years from now means about £416,000, and if only 10c. per lb.

of this is spent in this colony it means a circulation of R500,000.—Your truly, L. H. KELLY.

P. S.—I have almost forgotten to thank the Press for their advocacy and the interest they have taken in promoting and pushing this undertaking.

L. H. KELLY.

EXPERIMENT WITH TANNING BARK.

BLACK WATTLE ("ACACIA DECURRENS").

Elephant Nook, Nuwara Eliya, 18th May 1889.

DEAR SIR,—The conclusion I came to on receiving the analysis and valuation of the *Acacia decurrens* bark, was that let the yield be what it might, the cultivation would not pay. This opinion was based upon the cost of a shipment of cinchona bark. I imagine the cost of shipping acacia bark would be the same. Say that the gross proceeds of one ton of the bark of *Acacia decurrens* is R150 (the equivalent of £10 or £11 sterling)=6.7c. per lb. The shipment of cinchona bark cost me in local charges (rail freight, baling, shipping, marine insurance, custom duty, and harbour dues, &c.) 4 cents per lb. The home charges were (freight, interest on freight, landing charges, marine insurance duty, fire insurance, advertising and sale expenses, brokerage, commission, analysis fee, &c.)=2½ cents per lb. Total charges in case of cinchona and probably the same with acacia 6½ cents per lb. against a probable proceeds of 6.7c. per lb. A margin of 1.5th of a cent per lb. But even this margin disappears when we take into calculation that there was 10 per cent difference in the weight of the bark on which rail freight was paid and that actually shipped, and a further difference of 4 per cent between the quantity shipped, and that for which I am credited in the account sales. I send you enclosed the original copy of the analysis of the *Acacia decurrens* bark, and under separate cover the sample of bark alluded to in Mr. Wardrop's letter. I will write you again shortly, pointing out in what manner this experiment may have been misleading and higher prices be obtainable, and also giving you what information I possess regarding the cultivation as a fuel supply.—Yours faithfully,

WALTER R. TRINGHAM.

Certificate of Analysis.

Laboratory & Assay Office, 39, Lime Street, London, E. C.

I have examined a sample of "Mimosa bark, marked as under, and find the following to be the result:—Ex "Roumania": *Acacia decurrens* quill. No. 63 1 bag. Tannin per cent: 34.35.

G. H. OGSTON.

[We are greatly disappointed: we should not at all have expected the charges to be as much on a rough tanning bark, as on cinchona, a medicinal bark; and surely the expense of harvesting, drying, &c. is much less, while the yield of bark should be far greater on a wattle tree than from cinchona?—Ed.]

COTTON CULTIVATION IN CEYLON.

Colombo, 17th May 1889.

DEAR SIR,—We beg to hand you copy in English of a pamphlet in the vernacular, on cotton cultivation, that is now being issued for the information of villagers more especially, but as its contents will be of general interest at this time, we shall be glad if you will give publicity to it.—We are, dear sir, yours faithfully,

FOR THE CEYLON SPINNING AND WEAVING Co., LTD., DARLEY, BUTLER Co.,

Agents & Secretaries.

[The leaflet, which gives the very pith of the practical information required by the ordinary cultivator, will be carefully reprinted in our next issue of the *Tropical Agriculturist*.—ED.]

(CHEAP TEA AND TRANSPORT.)

DEAR SIR,—I do not know what is meant when you say "We know leaf has been bought at 8c per lb., but that was under 'exceptional circumstances.'" I know an estate that is buying ordinary good leaf—not fine plucked—at that rate.

The cart-hire to Colombo from Haputale estates to Fort is a trifle over $1\frac{1}{2}$ CENT per lb. net of TEA. Just as good as Dikoya with a railway, and it may be better. It may, I fear, be better than with a railway to Haputale.

Just received way-bill of tea from new Maturata, and the rate per lb. net of tea is positively more than from Haputale, although the Maturata tea comes by train from Kandy!—Yours, AGENT.

[But, if the cartmen had no railway competition, how would the rates be?—ED.]

"THE TERRORS OF THE TEA POT:"

"BY A BEER DRINKER."

May 22nd, 1889.

SIR,—The article you take over from the *St. James's Budget* in your Supplement of May 18th although racy, humorous and somewhat sensational, is one of that kind inserted for the amusement of London Clubs, and more for the way in which it is written than for the author's very misapplied thesis. The Chinese continue to be today, what they always were, the most industrious people under the sun. So much so that nations of European extraction like the United States and our British dependencies are so afraid of their competition, that they are obliged to legislate against the introduction of Chinese labour. As to their inventiveness, skill and fertility of resource in certain art work it is simply proverbial. "That they have no care for life, no fear of death, no considerations for human suffering" has nothing to do with tea drinking; it is the result of the ruin brought about by false theological teaching, idolatry and the survival of the effect of the brutality of all autocratic Government, though the darkness of past ages, and in the light of this. The Chinese knew for instance for hundreds of years before we did, in their exquisite pottery, called china, how to make it from kaolin, and that glass was made from the ashes of the fern. They were civilized in degree as it is termed, when Europeans, as represented by Goths and Vandals were savages, and today they still are in spite of the researches of chemists ahead or by no means retrograde in this direction, many of their ingenious processes being still secret.

But granting freely the deterioration physically of the human race, and that most of this is produced by its follies and excesses, how much is not due to beer drinking, to opium smoking, tobacco smoking, chewing and spitting, and the extensive use of narcotics, the effect of which is so marked? The spitting alone in chief cities of the United States, even in Boston, "the hub of the universe" and "the city of culture," is so constant that ladies have to hold up their dresses to avoid making pavement-cleansing cloths of them in wiping up the mess made by these filthy brutes, whose manners know no more excuse than to say "Wal stranger, I guess I cleared yer," when they miss spitting on passers themselves.

These are the over-active, nerve-destroying, body-destroying, and race-denerating agents—not tea. Men like "a beer drinker" are so fond still like the Pharisee of saying they are not what other people are, but forgetting they are tarred with the same brush. If the Chinese are deteriorating as a race, it is due to the excessive use of opium more than to tea, which they

have used and known just as long and just as extensively. The free use of these narcotics has been proved, not only to injure the nerves and poison the system, but absolutely to dwarf the human race. Suppression of their use is sometimes attempted by legislation, but in vain. I remember a special instance at the Cape of Good Hope, where "dagga" smoking among the natives was suppressed or an attempt made to suppress it by law on account of its pernicious effect, but with little success. This is a powerful poisonous narcotic which with about two draws from a "dagga" hole made in the ground from which the natives inflate their lungs will induce sleep and torpidity for hours. Living on roots, wild nuts, unwholesome animal food and "dagga" smoking has reduced the size of the aborigines in some parts of South and Central Africa among certain tribes to dwarfs, and by breeding in and in, the dwarf has continued to dwarf until a race of pigmies is found, descended however from the original sons of Ham of the normal size. In mind and body alike depraved and debased until unable at times to do more than sit on their haunches looking like idiots, to which the Darwins and modern infidels point in their folly, and call them "primeval man"! It is human degradation that is the true thesis and not "development" the true hypothesis.

But to place all this to the account of tea which when properly infused is not only harmless but refreshing, is certainly rather too bad. *Aprépos* of it, I had a travelled friend, who, seeing me well milking and creaming my tea when passing round after dinner, said: "Ah! that is the way to get indigestion; you should do as I do, following the example of the Chinese and Russians, they take their tea without milk." "Are you aware," he continued, "that the tannin in the tea unites with the milk and the cream turns it into leather?" Just what we want, thought I, and there is something in this worth observing. Tea with milk in it, I believe, has the effect of absolutely neutralizing if not destroying the action of the tannin.

So Great Britain, the land of milk, has learned, after all, how best to use tea without abusing it.—Yours truly, A MODERATE TEA DRINKER.

TEA PROSPECTS.

SIR,—The prospects of tea will give us all a shake: but will result in good. Planters will be forced to make better tea. I know that is my case. Have you heard of any syndicate or combination of China tea merchants to meet present heavy losses in order to secure future profits by ruining the present generation of British tea-growers? Yet what short of that could induce China buyers to ship home large supplies in face of the existing depression. Those individual firms will not face the certain loss: have they not suffered much already? The present deadlock may get even worse, but cannot last?—Yours truly, ANOTHER PROPRIETOR.

BLACK BUG ON CEYLON COFFEE OF RECENT YEARS.

Ramboda, 22nd May 1889.

DEAR SIR,—It is with the greatest diffidence that I venture to question a statement in the *Observer*; but surely, in your impression of 18th instant, when in a note you write: "Black bug ceased to affect seriously Ceylon coffee nearly 35 years ago," you, were unaware of this pest on Upper Ramboda estates within the last 10 years, before coffee was cut out. In Udapu sellawa also in 1877 we used the means of thatching the roots you mention, but the disease there was nothing compared to what I have seen in Ramboda. I can mention an estate now even in Sabaragamuwa where the coffee is

simply devoured by black bug. Of course though, it was nothing like the curse of green bug, and did not actually strip the trees, still it prevented the fruit from ripening by falling off before mature.—Yours,
C. L. R.

[We thank our correspondent for his correction, and useful information, well worth putting on record as the outcome of personal experience and observation. We were aware that "black bug" still lurked in certain corners of our higher districts; but in saying that it "ceased to affect seriously Ceylon coffee 35 years ago" we had the whole country in view. In the time of Dr. Gardner and for some years after, black bug prevailed so widely that many, along with the then Gardens' Director, believed it would gradually wear and kill out all the coffee in Ceylon.—Ed.]

KEROSENE EMULSION FOR SCALE INSECTS (BUG) ON COFFEE &c.

23rd May 1889.

DEAR SIR,—About a year ago I suggested in a paper published by the Agri-Horticultural Society of India, that kerosene emulsion might prove of service against the scale insects which of late years have done very serious injury to coffee in South India and Ceylon. The kerosene emulsion was afterwards tried upon green scale bug in the Nilgiri Hills by Mr. R. H. Morris, who found it entirely successful, killing the bug, wherever it touched it, on the first application. Kerosene emulsion has since been recommended for coffee scale by United States entomologists, and it is anticipated that it will prove the most satisfactory application for destroying this injurious pest.

Kerosene emulsion is made by mixing two parts of oil with one part of soap solution or milk (the soap solution being made by dissolving from a quarter to one pound of common soap, or whale oil soap, in one gallon of water). The whole is violently churned at a temperature of about 100° F. by driving it backwards and forwards through the spray nozzle of a force-pump. The emulsion thus formed is diluted with water, that used by Mr. Morris was made with common soap, and was diluted with nine parts of water. It is applied by spraying it over affected coffee bushes, and for this purpose an ordinary force-pump is most convenient, but must be fitted with a nozzle that gives a very finely divided spray. This being most important, both in order to save unnecessary expenditure of emulsion, and also because it is much more effective when sprayed in a cloud than when sprinkled in large drops. The best nozzle for the purpose is what is known as the Cyclone Eddy nozzle, consisting of a small circular chamber with two flat sides, the inlet through which the liquid is forced from the pump being bored tangentially through its wall, so as to cause a rapid whirling or centrifugal motion of the liquid, which issues in a funnel-shaped spray through the central outlet in one of the flat sides of the circular chamber. What seems to be an excellent force-pump, fitted with cyclone nozzles, has been sent to me for experiment by Messrs. Woodin & Little of 509 Market Street, San Francisco, U. S., and I am informed that cyclone nozzles can also be obtained from Messrs. Thos. Commerville & Sons of Washington, U. S., from V. Vermorel, Villefranche sur Rhone, France, from Messrs. Kitzner Brothers, Masterton, New Zealand, besides other firms in different parts of the world.

Kerosene emulsion was originally used by Messrs. Riley & Hubbard against the scale insect that attacks orange trees in Florida where it is now

widely adopted for this purpose. The cyclone nozzle is the invention of Dr. Riley, who has unselfishly refrained from patenting it.—Yours faithfully,
E. C. COTTON, Indian Museum, Calcutta.

TEAS FOR THE AMERICAN MARKET.

Colombo, 23rd May 1889.

DEAR SIR,—Your article of last night reads that I advocate cologns *exclusively* being shipped to the States: this is not the case. I would give green teas first place and then cologns. When I say green teas I mean pure, *uncolored* teas, free of course from all facing. It is quite possible to have green tea possessing all the cup characteristics of green tea without the coloring matter, and this is the class of tea I recommend to be shipped. China cologns are in no way coloured or adulterated.*

Statistics show that there is small consumption of black tea in the States, but it is only small compared with other kinds, and not sufficient to take off any weight on tea from the London market, already considerably overstocked and certain to be added to in the near future.—Yours very truly,
F. F. STREET.

JAPAN CEDAR TEA CHESTS.

St. John Del Rey, Bogawantalawa, May 23rd, 1889.

SIR,—With reference to the discussion as to the merits or demerits of Japanese tea chests, may I state that I have used the 'cedar wood' chests now for over three years, and have never had any complaint about them from our London brokers, Messrs. Wilson, Smithett & Co.?

It is, I think, only fair to importers of these chests, and is otherwise desirable, that facts such as these should be made known.—Yours faithfully,
GILES F. WALKER.

CEYLON TEA IN AMERICA: HOW TO PUSH IT.

Nawalapitiya, 23rd May 1889.

DEAR SIR,—In view of an Association or Company being now got up here for the sale of Ceylon teas in America, I would direct your attention to a letter signed "Star-Spangled" in the *Tropical Agriculturist* for August 1883. It was evidently written by one who knew his subject, and had made himself acquainted with the American tea trade, and the taste for tea of the American people. The letter is headed "Indian Tea in America."

I would recommend the perusal of it by all those interested, and especially by the Directors of the Co. referred to above, and to this end I think they could not do better than have it reprinted from your columns got up in a neat pictorial form (as to cover), and spread it broadcast over all the leading towns in America as soon as they are in a position to commence business there for the sale of pure Ceylon teas; for what applied to Indians would equally apply to Ceylons as a new introduction in any quantity to their markets.

In looking over some of the old numbers of the *T. A.* today I stumbled upon this letter, and I think it particularly worthy of being reproduced at this time.—Yours faithfully,
A. M.—N.

[The letter referred to covers two pages of the *T. A.* and is a capital account, with sarcastic remarks, of the difficulties experienced by an Indian planter in getting his fine teas even looked at by tea-dealers in America: this letter would no doubt open the minds of consumers considerably, if freely brought under their notice.—Ed.]

* While those of Japan are *invariably* faced and adulterated, and they count for 50 million lb. exported to America.—Ed.

TEA MAKING AND SUPERINTENDENTS
AND ACCOUNTS.

Ambagamuwa, 24th May 1889.

DEAR SIR.—If people would attend to their own business, and not rush into print on matters of no concern whatever to the public, I think we would all pull together much better.

One individual starts off with a childish idea, viz. that tennis, cricket, &c., have a deal to do with the fall in price of our teas, or in other words through want of attention to the manufacture. Comparatively speaking I indulge in neither, nevertheless, "let those who like it enjoy themselves," be my sentiments.

Now some other individual, who apparently considers he has discovered something quite new, wishes to inform the public that superintendents give cheques on account of the estate, to pay their private accounts. If they do, what on earth has this question got to do with the public? And besides where is the harm.

For instance, I have no bank account, and have not got the required sum to start one with. Well at a certain date my butcher duns me, and I find I have R200 due me by the estate. Immediately, I sit down and send him a cheque in payment of his claim, say R80, some one else duns me, and I do likewise.

Now, as long as I don't draw cheques to the amount above what is due me by the estate, where lies the harm?

Probably "Folly" has done it himself, so often, and to such an extent, that he has landed in a hole, and hence his signature, which sounds like "from experience."

However, let us hope the poor creature has learned a lesson; and until he can think of something else to write about, my advice to him is, "to shove his head into a bag and keep it there as long as he likes," for I am sure the readers of your paper won't object.—Yours faithfully,

DID HE DO IT?

CEYLON TEAS OF LATE AND THE LOCAL
BUYERS: A REBUKE.

Central Province, 24th May.

DEAR SIR.—I was much pleased to see Messrs. Forbes & Walker's sturdy disclaimer of the charge of *bad quality*, made by the several young tea-tasters, who purport to be judges as well as buyers of Ceylon tea, in Colombo. For the last three months these gentlemen have been exhaustively studying their dictionaries for newer and stronger adjectives to hurl at the staple, which it is clear they have now no orders to buy. One of them, to prove apparently how bad the teas have become, published a list of the epithets he and his kind have already applied to it.

One would, perhaps naturally, have expected to find this sweeping and general condemnation re-echoed from London. Yet we find that the market there has been taking off 1,000,000 lb. per week; and even in the teeth of such huge arrivals, the decline has only been from 10d to 9½d average during the last month; whereas here it has been at least 2d to 3d according to grades, and only a few thousand pounds find purchasers even at that reduction.

Hear then, ye would-be oracles, what the heads of your profession at home write on May 2nd:—"The great bulk of the recent import is of fair average quality, most invoices having nice fresh flavour and aroma, to compensate for a little want of strength, often noticeable, and we think this accounts for their generally good reception." These words appear

above the signature of Wm. Jas. & Hy. Thompson. The only thing you can plead, "ye oracles," is, that the teas have improved in transit, instead of deteriorating, as ye always tell us.

It is some consolation to the much abused teamakers to know that a firm of such standing appreciates their efforts. If they can make such good tea in March they would do equally well in April if the leaf naturally were equally good. It is highly diverting to see in one of your contemporaries how the planters are one day coaxed and flattered by being told that "We" always looked upon them as able to beat our Indian brethren, or any other body of men engaged in planting; and the next day that their low prices are entirely due to their vicious system of manufacture. ECHO.

TEA CULTURE AND PREPARATION.

26th May 1889.

DEAR SIR.—The public will, I am sure, fully appreciate the interesting information that has been elicited in reply to the questions I sent you, and I am personally under an obligation to you for so kindly circulating them. The general opinion seems to be:—

1. That the bushes produce the best tea when flushing *moderately* some months after pruning.
2. That both natural and artificial manures add largely to the yield, but they have not been found generally to improve the quality of the liquor.
3. That under normal conditions medium plucking pays best.

The absence of carefully collected data to *prove* beyond doubt the accuracy of opinions expressed, naturally detracts somewhat from their value, but the varying conditions under which tea is cultivated in Ceylon, render it exceedingly difficult to establish conclusions of a thoroughly reliable nature, which could be *generally* applied.

The respective merits of fine and medium plucking, however, might, by this time, have been determined with tolerable accuracy, if the two systems had been fairly tried; but so long as moderate treatment of the bushes resulted in good paying consignments, people were content to continue it, feeling that it was the best from an agricultural point of view, and they had no particular desire to establish a reputation for themselves at the expense of quantity.

From experiments I have myself made, there are not many estates in Ceylon where fine plucking can be continued for any great length of time without serious consequences, which manifest themselves both in the impaired vigour of the tree and deterioration in the quality of the liquor.

Then again there are a great number of estates where fine plucking at certain seasons of the year is an impossibility, and others where it would be difficult to make teas of exceptional merit, no matter what system of plucking were adopted.

All this goes to prove that no hard and fast rule can be laid down for the guidance of the tea planter: each estate must so to speak be dealt with on its own merits, and the advice of one of your Kelebokka correspondents to proceed on these lines, and make the most of any particular point which the teas develop (such as flavour, &c.) is thoroughly sound.

At the same time there is the commercial aspect of the case to be considered, and it is not improbable, that temporarily at any rate, the value

of the common grades may dip below the cost of production; in fact this has already happened in a number of cases, and we cannot expect any material improvement in the position of affairs until China retires from the scene.

In the meantime a great deal can be done towards improving the quality of our teas without seriously reducing the quantity, by insisting on good leaf being brought into the factory and good leaf only. By good leaf I do not necessarily mean *fine* leaf, but I state it as a positive fact that in nine factories out of ten the intake every day includes a lot of bany and hard leaf, which has no business to be brought in at all, and which being rolled off with the finer foliage causes general deterioration.

Buyers of leaf will bear me out in this, and many of those who do not buy are far less careful than they should be in insisting upon having the "leather" picked out, before spreading the leaf on the tats.

Given an adequate labour force, good leaf can be secured from almost every estate, but it will not be brought in unless insisted upon.

Experience will no doubt come to our assistance by and bye, but I am very strongly of opinion that the system which has lately prevailed in Ceylon, of allowing the bushes to run two and two and a half years between prunings, is another fruitful source of deterioration in quality. The leaves get harder and harder as the wood matures, and their association with the fine succulent flushes from properly-cared-for bushes *must* in my judgment do harm.

It is customary to sneer at the Brokers when they complain of an invoice of tea not being up to the quality of previous ones; but has it ever occurred to the Planter that the deterioration complained of exists and may be due to causes which are quite within the limits of control? If not, let him the next time his teas are badly reported on ask himself the question whether his bushes are in the order they should be, and how much bany and leather has found its way into his factory?

Some of your correspondents seem to doubt the possibility of combining quantity with quality. To such I would reply that it is impossible unless the bushes are kept in good order and the pluckers properly looked after.

The statement that fine quality teas are made in the field and not in the factory contains the essence of much that is true, and in the great majority of cases, it will be found that the men who succeed in getting good prices, and an abundant yield, are those who are constantly with their pluckers, and who know *when* and *how* to prune.—Yours faithfully,

PRACTICAL PLANTER.

COTTON AND OTHER PRODUCTS IN THE WATTEGAMA DISTRICT.

Wattegama, 27th May 1889.

DEAR SIR,—I noticed a short paragraph in your issue of 25th inst., wherein you state that I am reported to have said Wattegama district was not suitable for growing cotton on account of insects and rain destroying the bushes (no doubt pods were meant), and you were surprised that I should give up so easily.

Doctor Duke informed me in July 1887 that he had some Peruvian cotton planted on Middlemarch estate. It came on well at first, but as soon as the pods began to form, insects attacked it and he could get very little cotton from his trees, though what little he got was of good quality, so he was going to abandon the cultivation, but asked me to try it at Wattegama. He sent me some seed in August following, which I first planted in a nursery, then out in

the field: trees are from 10 to 15 feet high, and I took my second crop in March last, a sample of which I send by this post. You will find some damaged cotton in the middle of packet. As soon as pods form, the red beetle and small black ant will get in, make their nest and soon destroy the pods; if the insects are destroyed when they first appear on the bushes, before they enter the forming pods, then the damage would not be so much; but, there is an extra cost in labour. Our next loss is from showers of rain after pods begin to open: then showers are useful to us for all our other products except cotton.

It is simply because other products pay so much better than cotton in Wattegama district that I and others did not extend the cultivation: see last Kandy Agricultural Show. For general estate products: Goonambil, gold medal; Maria, silver medal; for fruit Maria gold medal. No doubt my friend Mr. Boustead was late before he began collecting his products, so perhaps lost the gold medal, thus proving what I always stated: one's eggs need not all be in one basket, but we grow all products in Wattegama, having the climate and soil: the latter though somewhat poor on surface is rich, deep and can be worked up to grow anything. Where before working it up nothing would grow, once in good order handsome profits can be made; but if you do not wish to assist young plants (which is contrary to all notions of cheap cultivators, though I proved the proper culture by practical experience) then keep away. Come and see Maria estate cacao, Rakawa tea and cinchona, Wattegama-watte cacao, coffee, and in which were old abandoned native gardens once. Please reprint the article on cotton caterpillars from *Planting Register* of 29th August 1887 for the information of present would-be cotton planters. Mariawatte, or Mariagalla as you wish the estate called, is planting some 25 acres of tobacco this year.—Yours truly, J. HOLLOWAY.

TEA SALES IN COLOMBO AND NEW MARKETS.

DEAR SIR,—If the Continental markets are to be opened, it seems to me it must be by direct shipments from Colombo to Continental ports, and therefore planters in their own interests would do well to let some of their *best* teas be sold in Colombo at auction, instructing the brokers if they buy in to offer the teas to Continental buyers at those rates, if they will guarantee that the teas shall be *shipped*, and shipped *not* to London, but to the Continent *direct*. In this way a good Continental demand may be gradually worked up; but if no good tea is to be got in Colombo, save at prohibitive prices, how is this much-desired state of things to be brought about.

OOLONGS.—Again, if planters begin to make these for the American market out of *coarse* leaf they will do only harm. Out of their fine leaf let them make their Oolongs for Jonathan, and if he has any palate, we'll capture the American market for such teas. PROPRIETOR.

TEA AT THE KANDY EXHIBITION.

Colombo, 27th May 1889.

DEAR SIR,—The decision of the tea judges at the late Kandy Show is, of course, like the laws of the Medes and Persians, unalterable; but may one ask the following questions:—

1st. Did Hoolankanda fulfil the conditions of the competition? I presume so, because otherwise no prize at all would have been awarded to it.

2nd. Was Hoolankanda up to its usual standard?

3rd. Were New Brunswick and St. John Del Rey better than usual?

My reason for asking these questions (certainly the last two) are obvious.

If Hoolankanda has fallen off, and is beaten by New Brunswick, and nearly so by St. John Del Rey

then of what use is fine plucking? because I am sure that both the proprietors of New Brunswick and St. John Del Rey will forgive my saying that they have not been in the "first flight" of the London averages, but Hoolankanda has been *facile princeps*. If on the other hand the plucking on Hoolankanda is the same and the estate has been fairly and squarely beaten, then surely there is "life in the old dog" yet, and the hopes of all connected with the prosperity of Ceylon will revive. Of course it is hardly likely, or possible, that the three gentlemen who have had the confidence of their brother planters can have made a mistake.—Your obedient servant,
INQUIRER.

MANURING TEA:—

A FEW PRACTICAL QUESTIONS.

Bogawantalawa, 28th May 1889.

DEAR SIR,—Your correspondent "F. D." was good enough to give in your issue of 24th some very interesting results of manuring tea, in my opinion the most practical which have yet appeared. Perhaps he would kindly supplement the information there given by saying how much cattle manure must be put to each bush; how much muck and how much castorcake when applied together, also how much double kainit when applied by itself. Has he ever tried applying the manure in holes between the trees instead of forking it in? People who have tried both ways say the holes are more successful than the forking, the roots not being so much damaged. Has he tried thatching with mana-grass after forking with or without manure?—Yours faithfully,
T.

WITHERING TEA LEAF.

28th May 1889.

DEAR SIR,—With every returning wet season numerous complaints appear in the *Observer* about the great difficulty of withering tea leaf. The brick flue would be a very simple and inexpensive system to overcome the difficulty. The flue—which would be heated from a furnace outside one end of the withering-room—could be built round by the foot of the walls or along the passages, or both, the whole length of the building, and turned backwards and forwards after as might be considered necessary to heat and dry the house: 7 inches square would be sufficient opening inside the flue, little fire would be required, the bricks once heated would keep hot a long time. If the flue system were something new, and someone had got a patent for it and charging a big price, it would likely have been largely in use before now; but because it is very old—probably the oldest system known for heating buildings from an outside fire—no one seems to have thought of it.

I see no reason why one—if he adopts the flue system—could not wither his leaf in wet weather in as short a time as in dry and at trifling cost. M.

CEYLON TEAS IN MINCING LANE AND THE PROFITS MADE AT HOME:

THE NEED FOR LARGE BREAKS.

Central Province, 30th May.

DEAR SIR,—The mail of 10th inst. confirms that of 3rd, and points to quite another reason than bad quality, for the fall in tea prices—viz., the physical impossibility to overtake the immense number of small breaks.

For this planters are certainly to blame, and the oracles have often emitted no uncertain sound or mystical hum on this point. The remedy is get larger bins.

Fancy, while the "poor but honest planter" has been getting less than cost of production, in many cases, London buyers have been scoring a return of 2d and 3d a lb. profit, by mostly buying, and immediately quitting!

It was this drop in London prices during the first week of May that caused the collapse of the market here, and let loose the *lees* in the stream of oracular abuse. And yet we find the drop due to bad judgment in breaks, and not to intrinsic deficiency of strength and flavour.

I think there is much source of consolation to us who bear the burden and heat of sun and factory, in the last four mails' London reports. Let us strive at once to remedy the very evident ruling defect. May the stocks of zinc sheeting be ample, and the holders thereof be men of conscience!—Yours faithfully,
ECHO.

CEYLON AND THE MANUFACTURE OF OOLONGS.

SIR,—I am sorry to see that you expressed an opinion the other day, with regard to Mr. Shand's shipment of Oolongs to America, that you thought it would have been better to have tried to open the American market with our ordinary make of black teas. In my opinion, our only chance, at first start-off, of getting the Yankees to drink our teas is to give them something like what they get from China and are accustomed to drink. You have only to refer to the enclosed Hong-kong Chamber of Commerce Circular to see that the shipment of Congous was only some 5½ million lb last season, whereas over 20 million lb of Oolongs were shipped; of China greens 14½ million; and from Japan over 22½ million (nearly all greens.) Greens and Oolongs very closely resemble one another in cup character.

It is no use trying to *force* a taste for an article which people do not know anything about, or to which they have not been accustomed. Ceylon planters, in the present unsatisfactory state of the London market, cannot afford to wait while a taste for our black teas is being *cultivated*. What they and we all want to see is the stuff being *consumed*, not going into stock to deteriorate. I have no doubt that a taste for our black teas will *come in time*, but it will take years before any quantity of black tea is consumed in the States. The introduction must be done *gradually*.

Having shipped large quantities of both green teas and Oolongs to New York from China, I think you will admit I ought to know what suits the American taste. Ceylon is capable of producing far finer green teas and Oolongs than China, and *will* do so when manufacture is thoroughly understood.
F. F. STREET.

Colombo, May 21st.

P. S.—I reported on some exceedingly fine liquoring green teas the other day from a hill-country estate. The make and grading were the only things that called for change.—"Local Times."

ANTILLES CHEMICAL MANURE WORKS.—Some few months back we had occasion to notice the above works, which were established in Barbados just ten years ago, and it is with pleasure that we now note the recent extension of this enterprise. Mr. H. E. Thorne, the proprietor, is determined the affair shall be a success; and, so far, everything has certainly answered his expectations. A whaling establishment has just been added to the works, and a good supply of raw material for the manufacture of the manures is now locally obtained in this way. Chemical manure works are by no means common in that particular quarter of the globe, but with its sulphuric acid works, the Antilles establishment is the most complete in the West Indies, and is increasing in importance every year. As a local industry, giving employment to a large number of hands in that densely populated community, it is deserving of continued prosperity and encouragement.—*Colonies & India*.

CINCHONA.—Our cinchona bark exports for the season at length shows a comparative decrease on that of last year, and very little is now arriving in Colombo from upcountry. There is some reason to hope therefore for a turn in the home market, but so far on sign has appeared of an advance in price.

JAVA SOILS.—Mr. J. H. Morrees, of Apeldoorn, has issued a prospectus proposing the establishment of an experimental station, for the purpose of examining the earth for Deli, Siak, and other places on the east coast of Sumatra. His object is to find out whether the physical and chemical condition of the soil is suitable for the cultivation of certain produce.—*London & China Express.*

THE DELI AND LANGKAT TOBACCO COMPANY, to which we referred last week, was registered by Messrs. Slaughter and May. The first subscribers were:—J. Pearson, 3, Oakleigh-road, New Southgate; W. Pitman, 7, St. Helen's gardens, S. W. C. Forde, 252, Cornwall-road; H. Warner, Beechcroft, Wimbledon; T. Spreng, 20, Spring Vale terrace, W.; W. May, 18, Austin Friars; and W. C. Slaughter, 18, Austin, Friars. Each of these takes one share.—*London & China Express, May 17th.*

GARNETS FROM MYSORE.—Garnets have gone up so much in the market lately, owing to the failure or exhaustion of the mines hitherto yielding this gem, that experts are being sent to report on all localities which are said to be garnetiferous. Mysore is known to produce garnets in abundance, but whether the gems are of any worth has not been ascertained. Mr. A. Streeter visits Sucklaspur, in the Hassan district shortly to report on the garnets of that locality.—*M. Mail.*

DUTCH BORNEO PROGRESSING.—In the S.-E. portion of Borneo, under the Netherlands flag, planting enterprise is gaining head. So many estates have been opened up there that a considerable demand for labour from Java has sprung up. This inflow looks strange, considering that from this very portion of Borneo a stream of coolie emigrants steadily sets in the direction of Deli. Evidently the local native labour prefers a foreign field.—*Straits Times, 5th May.*

GLOOMY PROSPECTS IN JAVA.—Java planters seem to be under a cloud quite as much as their brethren in Ceylon:—

The *Batavia Nieuwsblad* takes a gloomy view of planting prospects in Java at the present moment. The burden of taxation so weighs upon the planters that, unless the Government lightens the load, many tea growers and cinchona cultivators will come to grief. Java tea now fetches such unremunerative prices in the London Market that ruin stares planters in the face should the Government turn a deaf ear to them.

EXPERIMENTAL COTTON GARDEN.—We hear that Government intends opening an Experimental Garden for the cultivation of Cotton. A trial has already been made under official auspices in the neighbourhood of Mahara, but it having proved a failure, for what reasons we do not know, Government is now prospecting for land either along the Sea-side Line or in a dry district within easy distance from the City. There is also a rumour that the Alfred Model Farm will be planted up with Cotton by the Company already floated, but whether the soil there is quite adapted for the cultivation we do not know.—Local "Examiner."

HOW TO UTILIZE RUNNING STREAMS.—A new method of utilising the power of running streams has been devised by M. Tarn, a Russian engineer. His apparatus consists of an endless cable carrying a series of canvas cones which open and shut like an umbrella. The cable passes over a double drum on board of a ponton, and at the other end over a pulley suspended from a buoy. On the lower part of the rope the cones are opened and forced forward by the current of water, thus setting in motion a shaft or drum.—*Public Opinion.*

CURE FOR COFFEE LEAF DISEASE.—A Fiji correspondent writes as follows:—"A German here named Chas. Rebman has undertaken to cure coffee leaf disease in Ceylon, and has prescribed a remedy for it, so he desires me to get the information for him, as to what is the amount of award he is entitled to in case he succeeds in the cure; so you will oblige me by getting me this information at any time convenient to you." [We fear the German is too late: there is now no reward available in Ceylon for a cure, even if anybody here were inclined to believe in a cure for *Hemileia vastatrix*, which no one is.—Ed.]

TOBACCO AND CEYLON COMPANIES.—We find we were misinformed about all the pieces of land offered to the local Tobacco Company having been condemned as unsuitable: some we learn have been bought and will be planted next year. Mr. Vollar too is not opening and for this Company near Katugastota as a native correspondent supposed. The Director of the local Board are thoroughly practical men and may be depended on to do full justice to the interests of their pioneer Company, but in view of the great competition for "tobacco land," it is obviously not to their interest to make known at present what land they have bought and where they are going to plant.

A GEM-DIGGING COMPANY FOR CEYLON continues to form the subject of a good deal of local writing, as our pages show, and we certainly see no sound reason why English capital should be withheld from a proposal so feasible and which has so much to commend it. There are local Syndicates at work, and no doubt something will come of them, but it is surprising in the face of the many discouragements in Burma, and the facilities in Ceylon—celebrated for its gems and gempits over a wide extent of country—from time immemorial, that a Company for the Ruby mines of the former should be regarded so favourably; while the Rubies, Sapphires, Catseyes, Moonstones, &c. &c. of the latter should be comparatively neglected. This ought not to be the case.

LOWER UDAPUSSELLAWA, 16th May.—The wet season has kept leaf disease on coffee rather bad, but has almost done for green bug. It makes one's heart glad to watch the helpless half-hearted efforts it is making to get abroad. Many trees badly affected last year have quite thrown it off and are putting out fresh healthy wood. Estimates are likely to be exceeded and the warm showers are ripening up crop faster than we can gather it. Tea is flushing well, and young plants growing satisfactorily. Coffee stealing has been going on and with lots of pallam is now on the increase. It is hard to catch them and as hard to get a conviction, so we must try powder and shot on them: nothing acts so well. Labour rather short, many coolies having gone to the railway, thinking to make better pay. A deal of paddy in the villages dying from too much moisture.

SUGAR AS AN ANTI-INCrustATOR.—Colonel Potto, an Italian Engineer, has, it is said, recently made some interesting experiments respecting the employment of sugar as an agent to prevent the incrustation of steam boilers. The experiments were made in a boiler of 20 H.-P., and containing 126 tubes, and the results are stated to have been highly satisfactory. Two kilometres of sugar were introduced into the boiler every week. Formerly the same boiler used to become incrustated in a period of about six weeks, but at the end of a like period after the sugar had been employed it was found to be but slightly coated. After the boiler had been working continually for upwards of four months with sugar introduced into the water, a thin film of incrustation was found to be formed; but this was easily removed by washing.—*Indian Engineer.*

A COFFEE KING.—Mr. J. J. O'Donohue, the coffee king, appeared before the Assembly committee on Trades and Manufactures, Tuesday, (February 19th) in favor of the McCarren bill to prevent gambling in coffee. Mr. O'Donohue said that he was the oldest coffee merchant in the city of New York. He had been in the business for forty-five years. He had broken every corner in coffee started in that time. Since 1882 the price of coffee has almost doubled. He thinks that the gambling in futures has a great deal to do with the increase in price. After Mr. O'Donohue had delivered his argument the committee at once agreed to report the bill.—*Merchants' Review*, February 22nd, in *Rio News*.

INDIAN TEA NOTES.—Tea is doing well in Nowgong. Plucking is going on in Durrung. The weather has been stormy in Cachar. Weather hot and cloudy with high winds is the news from Goalpara. Seasonable weather is reported from Sylhet, Kamroop, Sibsaur and Luckimpore. Chittagong, 3rd May:—Chittagong has had fair rain during the week, but strong South winds have dried up some of the moisture. Charali, 1st May:—Rainfall to date, 13.92 inches against 14.69 inches last year. Gardens looking well, but more heat is wanted to bring on leaf. Cholera prevalent in several *bustees*, and on some of the gardens there have been a few fatal cases among the coolies. 8th May.—Our Habigunge telegram states that ample rain has fallen and other conditions are favourable, but the outturns still behind last year. An occasional correspondent writes under date 7th May:—The storms have simply been appalling. Leaf-houses, lines, and even bungalows have been blown down and nearly all gardens in North Cachar have been cut to pieces by hail. Moolydar will not recommence manufacture for 4 weeks, at least, Seebong for 6 weeks. The hail has been the worst I have seen in my 12 years' experience and many older men confirm it. There were over 21 in. of rain during the past week. Dehra Dun, 8th May.—Most gardens have stopped manufacturing and we shall not make any more tea till the rains. We have had a very good Spring crop.—*Indian Planters' Gazette*, May 14th.

TEA CULTURE AND PREPARATION.—The very interesting and practical discussion started by the questions circulated respecting the time at which the best tea is got in reference to the condition of the bushes, the effect of manures, and the best style of leaf-plucking, will be found continued—indeed we may say concluded—in our present issue. Some sixty-five well-known experienced tea planters have responded, and good can only result from this interchange of opinion and experience. The originator of the questions has also summed up the discussion and the general conclusion come to is that, while there is a good deal to learn yet with reference to certain departments of his work, the Ceylon tea-planter is well on the road if not to "perfection" at least to a high standard of working both in the field and factory, while his motto should be—as so well put by Messrs. Stenning, Inskipp & Co.—"Make good tea and as much of it as you can; but let the quality be good." In this connection we call attention to the article and table on pages 41-2, bearing on the actual cost of tea for production, manufacture and charges in Ceylon under a variety of circumstances, on old coffee estates or virgin land as indicated by crops of from 250 to 500 lb. of made tea per acre. The lowest rate in our table is 29½ cents f. o. b., and the highest 40 cents; but it is admitted that with a larger acreage than 250 acres—the standard taken for the table,—there could be a further saving, of one or two cents. We suppose 25 to 26 cents (4d per lb.) f. o. b., to be about the best attainable rate in Ceylon and that only in a few exceptional cases.

THE DUTY ON TEA.—Mr. Picton was very plucky to renew his motion for abolition; but it has been clear, ever since the Naval Scheme appeared, that nothing could be done this year. "Better luck next time"—when perhaps there will be no cheap China stuff to take advantage of a lowered duty, or free tariff.

GUM-YIELDING TREES are thus referred by Mr. D. Morris of Kew, in a letter to the Madras Agri-Horticultural Society:—

As regards seeds of *Acacia Senegal*, Willd., this species is said to be also a native of Sciud, whence Stock obtained specimens in the Kew Herbarium. Hence it may be Indian as well as African. *Acacia Verek* is supposed to be the same or very similar plant, and it is this latter which is described by Schweinfurth as yielding the best white gum of commerce, in fact gum arabic. We obtained after a good deal of trouble seeds of "true gum arabic" from Morocco in 1886. This was believed to be *Acacia gummifera*. Your Society had seeds of this species sent at the time, and no doubt you have plants raised from them. We shall endeavour to interest Dr. Schweinfurth in *A. Senegal* or what he calls *A. Verek*, and if we are fortunate to receive seeds, we shall be happy to send them to you. The opinion as regards many gum-bearing plants is that although they may grow readily enough in another country, there is no certainty that they will yield gum on a commercial scale. This is not difficult to understand if we consider that trees for the most part exude gum as a pathological phenomenon and not as a normal condition of their growth. The nearer the soil and climate of a country approaches those of the native country of gum-bearing acacias, the greater hope, of course, will be that gum will be produced. But even if gum is produced, we have to remember that gum in Africa is a forest product to be had for the mere cost of collecting it in extensive self-sown *Acacia* forests. Unless the price of gum arabic rises, very much indeed it is hopeless to attempt to grow gum-bearing trees in India on a sufficiently large scale to compete successfully with African produce.

We add notice of a letter from Surgeon-General G. Bidie, M. B., C. I. E., &c., dated Ootacamund, 28th April 1888:—

Perhaps the subjoined extracts from a letter received by me from the Museum Department of the Pharmaceutical Society of London, may be of interest as well as use to the Society. "Have any attempts been made to cultivate the Siam Benzoin which grows in the Laos states of Siam? The seeds grow readily, and the balsamic resin of the tree is worth from £50 to £90 per cwt.; the trees appear to be cut when about 6 inches in diameter. Mr. Jamie had a tree in his garden at Singapore, of which I should think twigs could be made to grow. It had not flowered when I heard from him." And again "There is an opening in the market in London now for a good gum of the character of the gum arabic. The qualities necessary are, it should dissolve entirely, give an adhesive mucilage, should not turn dark when a few drops of solution of iron are added to it. If iron darkens it, it does not do for calico printing one of its chief uses. The fewer bubbles it makes when poured from one vessel to another, the higher its value." Surely some of our indigenous gums if carefully extracted and dried, would answer these tests, and this is just one of those things in which a great deal of money might be made if any one would take the trouble to search and experiment. Might not the Superintendent of the gardens be asked to see what can be done in the matter and the results be communicated to the Press for the benefit of mercantile men, &c?" Resolved, that Surgn-Genl. Bidie be thanked for his letter, and that enquiries be made on the important subjects referred to by him. It is believed that considerable information on this subject of the various Indian gums is already available in several Government papers.

"GOOD TEA MADE IN THE FIELD."—A planter at a high elevation, who has maintained an average of over 1s. 1d. for upwards of 60,000 lb. of tea sold between July and February last, testifies that in his opinion "Good tea is principally made in the field."

CEYLON TEA IN NEW ZEALAND.—Mr. R. Andrews of Dunedin leaves by the S. S. "Rome," and he is much pleased to see the part taken by the Planters' Tea Fund Committee in voting £300 for a representation of Ceylon teas at the New Zealand and South Seas Exhibition. Mr. Andrews feels sure Ceylon teas will take in the Britain of the South, and no efforts will be wanting on his part in making their good properties and good value known among his friends.

INDIAN TEA AND THE COMING BATTLE.—The larger proportion of tea gardens in India being owned by Limited Companies, it is supposed that they can stand a struggle with low prices longer than individual proprietors. But to judge by the past history of tea in India, this is at least doubtful; for there is the precedent frequently noticed, we believe, of shareholders in Indian Tea Companies refusing to answer calls and proposing to allow tea acreage go to waste until a return of better times allowed of the bushes being once more cleared, pruned and plucked.

WHAT QUANTITY OF TEA CAN CEYLON PRODUCE THREE OR FOUR YEARS HENCE?—In our estimates hitherto, we have not ventured to go above 50 million lb. for season 1890-91; but we suspect now that, if there were only a market, 60 millions could be shipped for that season. Mr. Bisset, who has just left us, says that after travelling from Matale to Uva and up and down, and hearing what the planters say, he cannot help thinking that Ceylon will be turning out 100 to 120 million lb. four or five years hence; and he urges that if the Planters' Association made this plain and it was generally known, it would stop all further planting of tea in India and show the China tea merchants the need of winding up their business in the Far East and establishing buying agencies at Colombo as soon as possible. This may be worthy of consideration.

"THE BLACK COTTON SOIL."—Mr. J. Dent Young who, in his day, has travelled in every province of the island perhaps as much as any man of intelligence and observation in our midst, places the following note at our disposal. We commend it to the attention of the Cotton Company, intending cultivators and Government:—

"The notices I see regarding cotton have called to my mind an 'out of the way' part of the island, where the soil looked to me very much like what is spoken of as the 'black cotton soil' in the Bombay Presidency. The land I allude to extends for about 15 miles in length between Punakarai, the *ci-devant* Pooneryn, and Tunakai in the Northern Province. The soil is no doubt very rich, and if the seasons and climate there should be suitable for cotton, the region would be worth the attention of cotton planters. I have seen nothing like it anywhere else in Ceylon."

TEA WITHERING.—Messrs. John Walker & Co., in sending us an advertisement, very properly remark:—

"Here is the reply to some of the remarks in your leader of last night. What better answer can we give? It is surprising that these machines are not more largely availed of. Just read the extracts we give from planters' letters, especially the last one from Mr. Jamieson."

Nothing could be more attractive; but few individual planters, we suspect, can face the expense. There's the rub; and the only solution of the

difficulty we can see is in the coalition of a certain number of plantations to establish central fully-equipped Factories. Would it not be a good plan for engineers travelling in the planting districts to keep their eyes open for favourable sites for central factories and to suggest to neighbouring proprietors how such might be availed of.

INDIAN TEA NOTES, May 7th.—Cachar has experienced warm weather. Weather cloudy and cool is the news from Durrung. Tea is doing well in Sylhet; there is some slight damage from hail. Seasonable weather is reported from Kamroop and Luckimpore. The news from Goalpara is high winds with hot and cloudy weather. Tea is doing well in Sibsaugor. There has been muggy weather with rain nearly every day. Darjeeling, 3rd May.—Nice showers; favourable for growth. Sootea, 29th April.—The "chota barsat" has brought with it capital weather: 4.45 inches of rain fell during the week, but we had it as hot as they make it on the 24th and 25th. Gardens are looking well all round here, and this favourable change of weather should give us a busy May. Sonari, 27th April.—Weather very unsettled, heavy showers and sun alternating. Red spider has made its appearance on one or two gardens, Dehra Dun, 30th April.—A Correspondent writes:—Most gardens are well ahead of last year; as yet we have had hardly any hot winds. We have very little leaf left, and shall stop tea making in a few days.—*Indian Planters' Gazette.*

DR. WATT AND THE COCONUT PALM.—The *Madras Mail* devotes over a column to cutting up this official author, winding up with,—“It is absurd to blame the Madras Agri-Horticultural Society not for its own ignorance of the characteristics and importance of the tree—which has yet to be proved—but for Dr. Watt's extraordinary want of information about a subject with which an officer in his position ought to be peculiarly well versed. The *Englishman* does not pay much of a compliment to Dr. Watt's superior officers when it leads its readers to suppose that the Government of India has been content to remain in comparative ignorance until the year 1889, about a tree which contributes to the export trade of Southern India commodities of the value of 60 lakhs per annum. Treatises on economic products are only valuable if they are accurate, and certainly Dr. Watt's monograph on the coconut tree does not, in its present form, deserve to be admitted to the category of papers that are reliable.” Dr. Watts and other writers in India should get “All About the Coconut Palm.”

TEA NOTES.—Tea is doing well in Sylhet. Seasonable weather is the news from Kamroop. The weather has been cold and showery in Durrung. Stormy weather is reported from Cachar and Luckimpore. Weather damp and cloudy with rain every day is reported from Sibsaugor. Chittagong, 15th May.—Chittagong had heavy rain early in the month succeeded by strong south winds. There was good rain again last night. Darjeeling, 19th May.—A thunderstorm with heavy rain and a little sleet here last night. There was every appearance of the rain having been general throughout the district and especially so in the Terai, where want of rain has been most serious as regards crops of all kinds. Tea has suffered very much from drought throughout the Terai. I fear the hailstorm must have done a considerable amount of damage on Terai tea gardens, as it came from that direction. Sootea, 13th May.—The weather has been cold and rainy with hardly a blink of sun during the past fortnight. Growlers, however, have not everything their own way, as leaf is plentiful and red spider is clearing off. Rainfall to date is 17.99 inches against 15.25 inches last year. Two guns had good sport on Saturday and Sunday week. The bag was three big deer, a buffalo and a mitton, the latter both bulls. They had a most interesting interview with a tiger, but the result has not yet been ascertained.—*Indian Planters' Gazette.*

THE GROUNDNUT TRADE.—The S. S. "Star of Victoria," from Galle is at present taking in a consignment of 12,000 bags of groundnuts for the French market, after which she proceeds to Pondicherry for a further shipment of this commodity and then leaves for Marseilles.—*Madras Mail*, May 18th.

CEYLON TEA IN ABERDEEN.—The *Overland Ceylon Observer* of 10th April publishes a list of names of "Benefactors of the Ceylon Tea Industry," and first on this list is the name of Mr. William Westland, Aberdeen. The agency established at 53 St. Nicholas Street has the credit of being the oldest Ceylon Tea Agency in Britain.—*Aberdeen Free Press*, May 4th.

COFFEE IN S. INDIA.—We learn that coffee prospects in the Ouchterlony Valley are not as roseate as we were led to represent them a few weeks ago. Much of the spike did not open, owing to the rain being too late, and a lot of blossom failed to set. Thus, the 800 ton estimate for the Valley has already dwindled down to 500 tons, and it is likely this estimated crop may be affected by unforeseen draw backs later on. 500 tons is not even an average crop for the Valley and it is hoped better luck may attend the proprietors in the next year.—*S. I. Observer*, May 16th.

INSECTICIDES.—A correspondent, writing to a contemporary, says—I notice that in your last issue soot lime and hellebore powder are all recommended for the destruction of caterpillars, but perhaps it is not generally known that gas-tar is a first rate preventive which is better than cure. I have had whole plots of gooseberry bushes devastated by them, and also cabbage and cauliflower. Since I commenced to use gas-tar the caterpillars have not made their appearance, and it is both a safe and a cheap remedy for the gooseberry caterpillar and all others affecting green crops which are subject to attack.—*Indian Forester*.

COTTON is not to be (like tea) everywhere a success in Ceylon! At least we learn that Mr. Joseph Holloway of Wategama—an experienced persevering agriculturist,—has been so disheartened by the result of his experiments with cotton for a long time back, that he concludes that neighbourhood is unsuited for cotton. He has had to contend with "beetles" in dry weather, the report says, while the rains when they come spoil his bushes! But this reads like a very old story of planting difficulties, and Mr. Holloway is not the man we take him to be if he confesses himself beaten with the new product.

WESTERN JAVA CINCHONA COMPANY.—At the annual meeting of the shareholders in this concern, held at Amsterdam a few days ago, it was stated that there are now in the four Java plantations of the company an aggregate of 3,600,000 *Ledgeriana* and 150,000 *Succirubra* trees. The net profit for the year 1888, almost exclusively obtained on the sales of cinchona, amounting to 98,750f., was 37,812f., which admits of a dividend of 3½ per cent to the shareholders. In view of the falling of the quinine prices, experiments are constantly being made with other articles, and the coca plantations at Fjiseureuh and Bajabang are in a flourishing condition.—*Chemist and Druggist*, May 10th.

IS TEA GOING TO RIVAL TOBACCO in its own particular line? The Americans have, it appears, discovered the intoxicating properties of the un-infused leaves; and eating the raw tea is now said to be the latest fancy which has found favour with the go-ahead residents of the United States. The habit is gaining ground everywhere, and is stated to be far more pernicious than taking alcohol to excess, for its effects are more marked upon the nervous system, and ultimately prove more injurious to those addicted to it. The raw leaves, when taken in large quantities, produce a sensation of pleasurable excitement and exhilaration, like other stimulants, and then a wild form of intoxication,

transcending anything experienced by those addicted to ardent spirits and strong drinks. So, at least, it is asserted. The prevalence of the habit is said to be attracting a good deal of attention on the other side of the Atlantic. If tea is to be chewed and smoked as well as infused, planters will have to study the requirements of the new market.—*Homes & Colonial Mail*.

COTTON CULTIVATION.—If cotton is to do anywhere in Ceylon it ought to be in Uva: indeed the natives have already shown how good a staple can be produced there. The story is now—and it will be supported probably by our Wategama report—that cotton is more liable to the attacks of "poochies" of every size and degree than any other product in the hands of the planter! If so, God help the cotton cultivator, we should be inclined to say. But we do not believe the report, at least in reference to cultivation in a suitable, that is comparatively dry climate and good soil. There is nothing in the history of cotton cultivation in the Southern States of America—although "next year" is not unknown there, as a Louisiana cotton grower explained to us while travelling with him through the Shenandoah valley—or in Tinnevely over the way, to show that cotton cultivation is specially precarious. The idea has been started, and we think it ought to be carefully considered, that the Uva planters, during the period of depression in tea, while China and perhaps India are being beaten back, might well take crops of cotton off their tea land, holding it ready for the more permanent product after a couple of years say. There is also the hope that in Uva even more than in Mr. Blackett's field near Gampola) two crops of cotton in the year may be gathered. We hope so.

TEA.—The fall in prices is proving a sore discouragement to our planters as indicating a possibly still greater fall when our bigger crops come forward. If only the worst could be known with out intermediate suspense, there would be a general sense of relief. For, in the long-run, Ceylon men are, we think, confident that they can carry the day both for quality and quantity—that is they look forward in a few years, to having so large a quantity of tea, medium and good quality, to export, as must shut out China tea and stop the extension of planting in India. If it were known that Ceylon's exports should run on for the next five years in the ratio of 35, 47, 60, 80 and 100 million lb., the effect no doubt would be to concentrate attention more than ever on this island as the great tea country of the future, and to discourage planting elsewhere and any but the most temporary arrangements in connection with tea business at China ports. Attention is still given to the question of introducing Ceylon teas into the American market the local Company, unfortunately, is not yet in a position to start, but is expected to be very shortly when Mr. Pineo will at once leave for New York. Tea experts here have been impressing on our planters the necessity of manufacturing Oolongs and so adapting their teas to the prevalent American taste. Ceylon Oolongs have already been most favourably reported on, and there is no doubt that a considerable quantity of this kind is likely to be made and sent to the American market; but we shall be sadly disappointed if our ordinary black ("breakfast") teas do not meet with favour especially in the middle and Western States until they gradually become the chief beverage on the American Continent and in place of 100 million lb. of tea in annual consumption for North America we see 400 millions consumed with a steadily increasing demand!

TEA CULTIVATION AND MANU-
FACTURE.

Mr. Forbes Laurie, who has already given his opinion in answer to the questions we placed before him, is good enough to supplement the remarks offered in our special column—which he considers are not statistical enough—by the following very instructive comparison:—

MEDIUM v. FINE PLUCKING.

I should place much as follows, if the factory machinery were complete:—

Medium Plucking.

Cr.—Say,—By 100,000 lb. of medium tea
at 50c. R50,000

Dr. To maintenance of 300 acres at R44
per acre inclusive of superintendence,
weeding, pruning, buildings and all out-
lay except crop expenses R13,200
To plucking 400,000 lb. leaf at 3c. R12,000
To making 100,000 lb. of tea at 7c. R 7,000

R32,200

This leaves a profit of R17,800

Fine Plucking:

Cr.—Say,—By 40,000 lb. tea at 80c.... .. R32,000

Dr. To maintenance as above R13,200
To plucking 160,000 lb. leaf at 6c. R 9,600
To making 40,000 lb. tea at 8c.* R 3,200

R26,000

This leaves a profit of R 6,000

*The more tea made the cheaper the work; the delays consequent upon stopping and starting small lots are unavoidable, &c. &c.

MATALE TO BE A GREAT COTTON-
GROWING DISTRICT.

A well-known Matale planter writes:—

"This is the finest moist season Matale has had for years, and it will come to the front again. Cotton, however, will be its staple."

CHINA TEA: THE NEW SEASON.

It is reported from Kiukiang that the market has opened in Ningchow at Tls. 8 over last year, and in Keemun at about Tls. 5, the quality of the tea being 20 per cent better and the crop a large one. An unusually large number of chaaszes are going up to Hankow and in spite of very bad news from London, the usual rush will no doubt take place.

Information reaches us from the various tea districts, says the *Foochow Echo*, that the teamen are acting with the greatest caution in buying the new leaf, and that they seem to be bent more on enjoyment than business. The only district in which business has already commenced is the Peeling, where we are informed the picking of the new leaf began on Saturday ast.—*China Mail*, May 4th.

MARKING TEA CHESTS.

(By F. F. Street.)

In reply to the question *re* "marking" tea boxes, it is doubtful if the planter can make quite a certainty of the top being removed in London in all cases, but I think the following would insure it in most:—

Hoop packages all round *except* the lid. Mark your lid "Top," and place the estate mark &c. on the end of the package. Careful sitting in the first place so as to remove any dust and small flakey leaf is most important, especially in the leafy grades.

In order to prevent the packages being pilfered after leaving the estate, I would advise nails used for the lid being rusted before use—a nail slightly barbed at the top would make the drawing an impossibility without detection in Colombo. A highly polished nail does not take such a good hold of the wood as one rusted, and if the packages receive a severe jar, the nails are apt to start and the package get slack.

The object of hooping to my thinking is to prevent the bottom half of the package coming away from the top half which the weight of the tea inside the package is apt to cause, when the side planks are of two or more boards. The weak place in a package is at the join of the side planks and not at the top or bottom.

The object I have in view in recommending the lid to be left unhooped is to save the wharfingers the trouble of cutting and removing when opening for brokers' inspection. It is reasonable to think that the Wharf people will remove the top in preference to the bottom, as it will be an easier operation.

CEYLON UPCOUNTRY PLANTING REPORT.

LOW PRICES AND TOO MUCH ADVICE ABOUT TEA—A PERSONAL ANECDOTE—NATIVE INDUSTRIES UPCOUNTRY: SINHALESE LANDLORDS AND TAMIL TENANTS—COFFEE BUG—CACAO PROSPECTS—WEATHER.

21st May 1889.

As the price of TEA in the London market recedes the planter's advisers are in the ascendant. They seem to represent all classes, but chiefly the foolish, and if it were not rather worrying, one would be lost in amazement at the wealth of wisdom displayed by some of this outside world. Every tag-rag-and-bob-tail Solon seems at present determined to deliver his soul on the follies of the tea planter: we are purblind and inefficient, play lawn tennis and cricket instead of attending to the tea-house, our teas are bad, and we need to be told—heaven help us!—that we are not worth our salt if we don't strain every nerve to keep down expenditure. Now I don't think that there is any of us who blink the seriousness of the times, and who do not see that we have a long and a heavy pull before us and act accordingly; but is the rubbishy stuff in the form of advice with which we are daily deluged and more than satiated likely to do any good? Is it for a moment to be thought that the planters alone are unable to see and think for themselves, and that they need outsiders to take up their parable? Is all this loving care and tender solicitude for our welfare, from a source that is pure?

It reminds me of an incident that once happened to myself. I was four minutes late for my train in Colombo, and it was just moving off as I drove up. It was evident at a glance how matters stood, and there was nothing for it, but to return to my hotel. This I would willingly have done without any display, but was prevented owing to the number of people who took an interest in the untoward state of my affairs. It was very touching. "You have lost your train," shouted one man as he drove past. "You can't get away till tomorrow now," cried another. "Five minutes would have saved you, pity you had not had a better horse," remarked a third. And yet I did not know a soul of them, and if I had not lost my train I should have been unnoticed. What created all this interest? was it sympathy, regret, or what? It seemed to me that it was but a rejoicing over my discomfiture; there was nothing helpful in it. Many of the suggestions and a good deal of the advice which of late have been gratuitously tendered to the tea planter is pretty much on the same footing. As to its value—why the historic two-penny d— of the late Duke of Wellington would

be a high figure to pay for bushels of such inane counsel. Those who feel that they have a call to speak should consider first of all if they have anything worth saying, and if not, better not.

The system which was very common in the palmy days of coffee, of the Tamils leasing land from Sinhalese for the cultivation of that product, is being revived again in the Central Province. Only the product is changed, and instead of coffee, COCONUTS and CACAO are the trees planted. This is principally done within the reach of towns or the railway, and the lessee cultivates plantains and vegetables, and from that hopes to make his profit. The owner of the land has to provide the seed for the coconuts and cacao, and at the end of eight years he takes back his property, paying to his tenant $12\frac{1}{2}$ cents for every cacao tree and 25 cents for each coconut. The growing of the vegetables, I am told, is rather a paying thing, and the traders who supply the markets take delivery of the produce at the garden, and in wholesale quantities. The blocks of land taken up are from 10 to 20 acres, and have all to be planted. Both Tamils and Sinhalese are taking to this.

COFFEE in this district—what there is of it—alas! that this should have to be added—is very luxuriant, but there is some bug about. That pest, those who have tackled it, and suffered from it, feel that it is one of those things that should be left to Providence. For “vain is the help of man.” So if you do anything to your coffee with that enemy about, it should be done in a reverent spirit, and with becoming humility.

The prospects of CACAO are very fair, grand blossoms out, and the trees looking exceedingly healthy. It's a comfort when there is something doing well.

THE WEATHER continues all that can be desired, and the tea goes on flushing as if there were no dull markets or lagging sales. All that you hear from Colombo is of a depressing nature, and the condition of the local market could hardly be more unsatisfactory than it is at present. We are told that London orders have to a large extent been cancelled, but we go on manufacturing. We aim to supply the world with the best tea, and in due time will do it.

PEPPERCORN.

OOLONGS AND GREEN TEAS VS. CEYLON BLACK TEAS FOR AMERICA.

We have come across a statement from the *American Grocer*, copied into the *Tropical Agriculturist* of April 1884, which, being we believe fairly accurate in fact, might be used with good effect by the Ceylon-American Tea Company in their approaching crusade. If oolongs and green teas are really more trying to the nerves than our ordinary fermented teas, the sooner excitable New Yorkers and New Englanders generally give them up in favour of superior Ceylon “breakfast” teas, the better! We quote as follows:—

We divide China tea into three general classes, viz:—Green, or unfermented tea.

Black, or fermented tea, sub-divided into Oolongs and Congou, the former subjected to slight and the latter to great fermentation.

Scented, also fermented.

Fermentation turns the leaf black, and in a measure destroys that quality in the tea which produces wakefulness and affects the nervous system. Hence it is that unfermented or green tea is a greater excitant of the nerves than fermented or black tea. Therefore Congou tea is preferable to Oolong, and that in turn to green.

Upon the island of Formosa is grown the Oolong variety bearing the island's name. It is extremely popular in this section of the United States.

Scented teas are known as Foochows or Cantons, the former divided into scented orange pekoe, scented capers, the latter the same.

PLANTING IN THE LOWCOUNTRY OF THE WESTERN PROVINCE :

RAINFALL—COCONUTS AND THE LEAF DISEASE—SALT AND COCONUT ENEMIES—PEPPER GROWING—BIG MONSOON.

HAPITIGAM KORALE, 13th May 1889.

Our dry season closed with the end of February, since which date our rainfall has been ample. 12 days in March gave 9.32 inches, April 19 days 14.62, and May up to date in 8 days in May 7.28. Total since 28th February 31.22 inches. Our heaviest storms gave 3.13 inches on 3rd March, 3.76 inches on 19th April, and 4.72 in, on 7th May. The abnormal drought that took place last year between the middle of June and the middle of October has been seriously injurious to young coconut fields, most of the plants having lost more leaves during the year than they opened, and there is no doubt the disease that appeared at its close is due to its long continuance as the immediate probably not the ultimate cause.

Every instance of the leaf disease that has come under my notice is associated with a compact impermeable subsoil, not easily penetrated by the roots, and affording little moisture and less aliment. I am convinced that the disease is in the roots, and that the appearance on the leaves is only an effect. If the injury be confined to the outlying roots the trees will recover; if the crown, from which the main roots spread, be affected, the tree will probably die a lingering death. Some of the affected trees have developed clean and healthy leaves since the rains came, but the latest opened leaves of others are thickly studded with dark spots characteristic of the disease. The first tree on which I observed it about two years ago was more advanced than those lately attacked; it seemed in the fair way of getting over it, but the relapse looks very much as if it would finish it: the last developed leaf is much smaller than its immediate predecessor and closely covered with spots. Though the young plants suffered severely on the dry gravel soils I have not there observed a single speck of this disease. As the disease did not prominently manifest itself during the drought, but forced itself on the attention of planters after the copious rains that succeeded, stagnant water about the previously dried up roots may have had something to do with the attack. In my own case neglected cultivation was not in fault, for the only field in which it has appeared on my property was dug over to the depth of nine or ten inches within the year.

Perhaps “W. A. D. S.” will tell us at his leisure what insects injurious to the coconut tree are killed or banished, by diluted smoke, and whether phytological science teaches, that ammonia, nitric acid and watery vapour are absorbed by the leaves of plants. We would likewise be glad to learn what weight of copra yields 12.204 grains of ashes.

My plan of growing Pepper on low bushes is not progressing so satisfactorily as I hoped. I put down 1,000 cuttings six months ago, and have tended them very carefully since, but not above 50 plants will be available for the field. I still believe the plan to be practicable, though I am rather put out of heart by the indifferent success in my first experiment, but I hope for better luck next time.

May 15th, 1889.—The big monsoon took form yesterday in a series of short showers: unusually early, isn't it?

THE AUSTRALIANS are about to undertake mining operations on a large scale in New Guinea. The Raub Mining estate near Punjore in the Pahang State has been sold to an Australian Syndicate for £230,000.—*Pioneer*.

TOBACCO CULTIVATION IN CEYLON.

(From a Correspondent.)

The lands of the German Syndicate at Wataluwa (Davis's Ferry) are being rapidly cleared. The Company have already secured about 120 acres, and 60 acres have been planted. They are negotiating for more land around and at Katugastota towards the railway station. Tobacco in the Kospotuoya Valley in the North-Western Province has been harvested and the leaves are undergoing the process of curing. Mr. Schappe, who had experience in Sumatra and the chief manager here, had a bad time of it with fever. Mariawatte is taking up tobacco too—50 acres are to be brought under cultivation, and the venture, it is hoped, will be equally successful as in the case of tea. I saw a plot of land in tobacco at Bandarapola about March. The plants looked well enough under such a fierce sun as was blazing then, but the ground was like brass. I wonder if the shrubs pulled through the drought. Mr. Alexander Ross has taken up a tract of land in North Matale in Damana-hena for tobacco, and operations are going forward most energetically. The land is said to be exceptionally good. Mr. Vollar has now, it is said, a shipment of between 30,000 and 40,000 lb. afloat, and you will recollect that it was his tobacco which being sold in Holland attracted the attention of Mr. Fritz Meyer, the head of the German Syndicate to Ceylon. So far the success of tobacco has been assured. The selection of the land is the principal thing to be seen to. Tobacco likes good soil, and worn-out land where tea can fight its way is unsuited to the fragrant weed.

HORSES:—A WRINKLE.

When travelling long ago, as I often did, by dak garee, between Lahore and Rawal Pindi, I remarked and wondered at the fact that frequently the *chowkee*, or place of changing, was two or three miles distant from the stable; an arrangement which I used to regard as an unwarrantable infliction of extra labour on ponies which appeared to have quite enough work to do in their own legitimate line. I am now, however, strongly inclined to think that whoever devised this means of obliging the syces (or *balgeers*, as they are called on that road) to lead their ponies for two or three miles, after doing their turn of fast work, had the health and welfare of these little animals at heart. I believe any horse, racer, or hack, when he comes in after his task, should have his gear loosened, and he should be walked about till he is dry. A minute's halt for a scrape and whip down might be allowed; but no elaborate drying, as is the custom in the rubbing-down sheds on Indian racecourses. These sheds for rubbing-down purposes after a gallop are relics of a custom that has died out of England more years than I can remember. Again I say, have the gear loosened, and the animal walked about until he is quite dry; no matter how far or how fast he may have gone, and then, and not till then, put him in his stable. I give this advice more with reference to the animal's legs and feet than to his general health. In my book on "Training and Horse Management in India" I have drawn attention to the good effects of giving a horse a moderate drink of water immediately after fast work. The hotter he is, the sooner should he get his water. I see that many trainers in India are of a different opinion; probably this small detail entails too much trouble to be carried out by them.—*Hayes' Sporting News.*

TOBACCO PLANTING IN DELI.

The *Delhi Courant* states that the Planters' Association there have rejected a motion binding the members not to engage coolie old stagers unless through the Immigration Office.

A Government interpreter for the Chinese language was lately to be despatched to the Celestial Empire for the purpose of furthering free emigration of coolies from there to the East Coast of Sumatra. The intended mission has for the present fallen through.

On Mr. Kohler's tobacco estate, a fermenting shed was set fire to the other night by evil disposed persons, after the piles of tobacco inside had previously had petroleum poured over them. With the utmost exertions the manager and his assistants succeeded in so far frustrating the design of the incendiaries that two-thirds of the shed were rescued from the flame. The damage done is, notwithstanding, very great, owing to the tobacco drenched by the petroleum being of course unserviceable.

The shipment of the tobacco crop raised last year is being actively proceeded with, so that most of the produce of the estates is already on the way to Europe.

The weather in the planting districts during April characterised itself by great heat. Drought has been the prevalent feature of the month. The consequence is that on most estates planting operations have been considerably delayed.—*Straits Times*, May 15th.

DATES, MAHOGANY, BAMBOOS, RUBBER
&c. IN SOUTHERN INDIA.

From the Madras Forest Administration Report for 1887-8 we quote as follows:—

Exotics.—The results of the experiments with exotics have been given in separate appendices. Germination from the seed of *date* fruits purchased in the bazaar was good and the plants appear to stand transplanting well; in both these respects, they are fully equal to the specially-imported seed and offsets; of the latter, 417 are alive of the 517 received in the Southern Circle in 1886-87, and are said to be looking healthy; the difference in the percentage of casualties even in plantations in the same district, as in Tanjore, seems to show that some of the loss was avoidable: the dates are reported to do better on the sandy soil of the East, than in the wet climate of the West Coast. Nothing is said about fruiting, and the formation of plantations on an extended scale was postponed to the present year. Wherever they have had a good soil and moist climate, *mahoganies* have done well: in Nilambur, a tree, 14 years old, is 71 feet high and 46 inches in girth, at breast high; in the Kullar range, trees planted in 1885-86 have attained a height of from 10 to 14 feet; in Wynad, plants planted out in the year, average 3½ feet in height, and in Trichopoly, plants obtained in 1886, range from 8 to 11½ feet high; in poor and dry soil, the growth is not good, and in Sriharikot the plantation is said to be a failure; as with the dates, much of the loss appears to be due to want of either care or experience in transplanting and tending, and is probably avoidable; the plants suffer badly from borers and beetles; in private gardens in Madras, e.g., Mr. H. O. King's, they grow luxuriantly.

The giant *bamboos* in Wynaad made vigorous growth: the various *rubber* plants and the *Ipecacuanha* there, also did well; the latter was tested by the Government Botanist and found to yield excellently. The commencement of what promises to be a successful experiment was made with *Sappan wood* in Wynaad, 2000 seeds being planted out and germinating without a failure: a few *eucalypti* have grown at heights down to 2,500 feet and are said to be doing well; they seeded at Pannanor; 78 *olive* trees, a foot high, raised from seeds sent in 1886-87, are also in the Wynaad nurseries; in the same place, *Lancewood* seems to have been a failure.

COFFEE AND TEA :

REASSURING NEWS FOR PLANTERS.

We think we can fairly call attention to several letters (pages 30-31) as embodying reassuring, if not cheering intelligence, for many of our planters. We may first refer to the communication from Mr. Cotes of the Calcutta Museum in reference to the use of "Kerosene Emulsion" as a check for the ravages of scale insects—the great "bug" family which, whether black or green has done, and is doing so much mischief to our coffee in Ceylon. We are aware that a good deal has been done already with kerosene and lime or soap mixtures on some coffee estates in fighting green bug, and although at least in one case—that of the group under the care of Mr. W. B. Jackson of Agrapatana—good results were obtained for a time from washing the stems of the coffee bushes with such a mixture; yet experience did not prove it to be such a cure as would warrant general application or repay all the outlay. On Capt. Bayley's estate, Nonpareil, too, kerosene and caustic lime have been freely used with results more or less satisfactory. The novelty therefore in the case of Mr. Cotes' letter lies not so much in the emulsion recommended—although it may be an improvement on local mixtures used hitherto—as in the means of application. True, we are told Mr. R. H. Morris on the Nilgiri Hills found that the kerosene emulsion killed the green bug wherever it touched it on the first application; but we are not told what was the extent of garden or estate which Mr. Morris cleared of the obnoxious insect, and whether the riddance was a permanent one.

It is, however, in the American contrivances for the economical and efficient distribution of the "emulsion" that we seem to see a possible opportunity of fighting the dread enemy of the Ceylon coffee planter of the present day, green bug. On Mr. Cotes' letter, we should like to have the opinion of men who must have given their enemy, "bug," very careful attention from nearly every point of view and who are specially interested in conserving the coffee still remaining to them. Among these, are Mr. Dick of Ragalla, Mr. Giles F. Walker of Dikoya, Mr. W. B. Jackson of the Agrapatana, and Mr. E. E. Green of Pundaluoya. Their opinion in response to Mr. Cotes cannot fail to interest and even enlighten that gentleman, as well as to be of benefit to their brother planters.

Turning to TEA, we have once more a cheery letter from our correspondent "Echo" which is certain to brace up and encourage his brother planters. So far from preaching pessimistically, he wants them to pull down (not their barns but) their bins and

to build or construct greater ones. He gives good reasons for asserting that "big breaks" of Ceylon tea must more than ever be the order of the day, and he shows how continuously favourable of late, have been the professional reports from home on our teas. In this connection we may quote what Messrs. Stenning, Inskipp & Co., the well-known brokers, report in reference both to Ceylon and Indian teas. Writing of the former (Ceylons) on the 9th instant, they say:—"Buyers experienced much "difficulty in valuing the large number of samples "and some irregularity in prices ensued." In their Indian Report of the same date, there are several paragraphs very much to the point and we reproduce it in full in our Commercial column. It will be observed that they estimate a less import from China by 14 million lb. against an increase of 10 millions from India and 11 millions from Ceylon. The latter calculation will prove rather below than above the mark we suspect; but allowing for 3 millions less export, Messrs. Stenning, Inskipp & Co. work out a total of 197 millions as likely to be available for "home consumption" in season 1889-90 against 187 million lb. in the season just closed. There is nothing very formidable in this return. What is said of Ceylon teas taking the place so largely of China teas, shows how keen must be the competition henceforward in this direction. While recommending "moderate plucking" to Indian planters, the brokers under notice, do not make the mistake of insisting on or advocating fine plucking and fine teas only. On the other hand they coin a phrase which must meet with general approval among planters and which coincides with the opinion lately arrived in our tea districts in favour of "medium plucking," namely:—"Make good tea and as much of it as you can; but let the quality be good."

In this connection,— "medium plucking" being the acknowledged best rule for Ceylon planters,— we have been favoured with a copy of a table prepared by Mr. F. M. Mackwood after consultation with several well-known upcountry tea authorities which we have pleasure in reproducing as affording a standard of guidance for many of our planters. It must be remembered that this table was compiled while prices were fairly prosperous and before the screw was put on by the recent fall in values. Consequently there is unquestionably room with strict care and economy, to work under the limits given. Of course the various authorities connected did not see eye to eye even in better times, as to each detail specified; but they all agreed as to the final result per lb. f.o.b. arrived at, and also as to the fact that on larger estates (say of 400 to 500 acres and upwards) one or two cents per lb. might be saved on the rates given. The suggestion has been made that Ceylon tea planters if pressed further should endeavour to reduce their coolies' pay a few cents per day; but both proprietors and experienced managers must feel this would be a very risky expedient to adopt at the present time when labour is by no means overplentiful and when we have to face a large area of planted tea land not yet in bearing. Before talking of reducing coolies' wages, we must see how far current rates will serve to attract an increased number of immigrants to attend to the plucking off 200,000 acres of land which must

erelong be cropped for tea in Ceylon.—Mr. Mackwood's table referred to above is as follows:—

COST OF REPRODUCTION OF TEA IN CEYLON:									
[On an Estate of 250 acres in full bearing, having good factory, adequate machinery and fuel on the Estate, F. O. B. Colombo, at rates of yield, from 250 lb. to 500 lb. per acre.]

[On a larger estate, say of 400 acres, Cost might be reduced 1 to 2 cents per lb.]

COCONUT CULTIVATION AND SALT. (Communicated.)

We are now in the midst of one of those periodical revivals of the salt question, that break out at intervals of about twenty years, and the manual value of salt is being lauded with more zeal than knowledge. It is not indeed probable that recent writings will lead to any very wide application of this substance to coconut land; yet it may not be out of place to counsel caution in its use, even were it to be had at its untaxed value. As salt

* Larger yield and expenditure. † Further increase. ‡ More coolies and lines. § Still more coolies. || This is full high rate. ¶ High rate.

is a constituent element of the coconut tree and its products, its total absence from the soil would result in total sterility; but one ounce per annum is probably ample for the constitutional needs of the most fertile tree, but not to scrimp the measure, let us say one hundredweight per acre every twelfth year. Admitting for the sake of argument that an unlimited supply of salt in the soil will not injure the coconut tree, yet why lock up capital in an inconvertible commodity? The advocates of large doses, however, tell us that the constitutional wants of the plant form only one part of the benefit to be derived from a heavy proportion of salt in the soil. We are told that it destroys weeds, it kills insects, it absorbs moisture, and has beneficial chemical effects on the soil. We want to know the exact measure of salt that will destroy coarse and useless vegetation without injury to the useful and valuable. What species of insects are killed by salt and the quantity required for that purpose? We want to know whether or not in the state of the atmosphere in which salt absorbs moisture, the soil retains too little for the needs of vegetation; whether or not the moisture absorbed by salt in the soil is immediately available to the roots of plants, and whether the moisture is retained in the face of a blazing sun and a blistering wind. As regards beneficial chemical effects, the experience of all ages has associated a soil largely impregnated with salt, with utter barrenness and desolation.

With such doubts as are above suggested before his mind no duly cautious planter will rush into salting his land till he has learned a great deal more than recent writers on the subject can teach him.

NATIVES CULTIVATING TEA IN PATANA LANDS.

A planter writing from a Northern district says:— "The amount of patana land that natives and others have put into tea since — has proved a success, is extraordinary, but whether in these times their gardens will ever come to anything is the question? The native used often to grow coffee in this way, and often let it slide, even when prices were good; and I incline to fancy when the state of the tea market filters down to the villagers' level, a lot will be abandoned. As it is, you hear of estates that have not done well being or going to be abandoned."

AGRI-HORTICULTURAL SHOW AND INDUSTRIAL EXHIBITION, KANDY.

MAY 24TH AND 25TH, 1889.

The prize-giving came off at 5 p. m. The prizes were distributed by Mrs. Moir. The Hon. Mr. Moir was also present, Mr. Crawford reading the names of the prize-winners:—

PRIZE LIST.

CLASS A.—PERENNIALS (in pots):—Best arranged table of plants, grown in Kandy and neighbourhood (12 feet by 8 feet), 1st prize, gold medal, not awarded; 2nd prize, silver medal, W. Penny; 3rd prize, silver medal, not awarded. Best arranged table of plants grown upcountry (12 feet by 8 feet), 2nd prize, A. Whyte. Best arranged table of plants, grown by "stationmasters, Ceylon Government Railway" (12 feet by 8 feet), 1st prize R15, J. R. Greve; 2nd prize R10, B. P. Perera. Begonia, single specimen, silver medal, E. V. Moonesinghe; Geraniums and pelargoniums, not less than six different kinds, silver medal, J. A. Morel.

CLASS B.—ANNUALS (in pots):—Best arranged table of plants, grown in Kandy and neighbourhood (12 feet by 8 feet), 1st prize, silver medal, not aware; 2nd prize, silver medal, W. Penny.

CLASS C.—FERNS (IN POTS):—Best arranged table of plants, not less than 12 different kinds (12 ft. x 8 ft.), 1st prize, gold medal, Gabriel Perera; 2nd prize, silver medal, W. Penney. Best arranged table of plants, grown by stationmasters, C. G. R. (12 ft. x 8 ft.), 1st prize, R. S. J. R. Greve; 2nd prize, B. P. Perera; Single specimen, silver medal, Dr. Morgan; Ditto, extra, H. J. Vollar.

CLASS D.—FOLIAGE PLANTS (IN POTS):—Best arranged table of plants, not less than different 18 kinds, (12 ft. x 8 ft.), 1st prize, silver medal, Mrs. Alexander; 2nd prize, silver medal, A. Whyte. Collection of coleus, silver medal, Mrs. Alexander, 1st prize; Charles Young, 2nd prize. Single specimen, Foliage plant, silver medal, J. C. H. George.

CLASS E.—CUT FLOWERS:—Best arranged table, grown in Kandy or neighbourhood (8 ft. x 4 ft.), 1st prize, silver medal, Mrs. Alexander; 2nd prize, silver medal, D. H. Perera. Best arranged table, grown upcountry (8 ft. x 4 ft.), 1st prize, silver medal, A. Whyte. Roses, not less than 12 different kinds grown in Kandy or neighbourhood, 1st prize, silver medal, A. R. Greve; 2nd prize, bronze medal, A. Whyte. Roses, (3 blooms) yellow, silver medal, W. Penney. Roses, (3 blooms) white, silver medal, Miss Wöth. Roses, (3 blooms) dark red, silver medal, A. Whyte. Arranged floral table decoration, (3ft. x 3ft.), silver medal, Miss Edith Tranchell. Hand bouquet, (to be awarded on both days), 1st prize, silver medal, A. O. Tranchell; 2nd prize, bronze medal, Gabriel Perera and A. Whyte. Button-hole bouquets (3), 1st prize, silver medal, J. H. Senawiratne; 2nd prize, bronze medal, Miss E. Tranchell. Table arrangement of native flowers (3' by 3') 1st prize, silver medal, D. C. Gunatilaka; 2nd prize, bronze medal, D. H. S. Gooneratna. Hibiscus, best collection, not less than 6 varieties, silver medal, W. Penny. Dahlias, extra prize, Mrs. Alexander; Pinks and dahlias, extra prize, Mrs. Alexander; Balsams, extra prize, Mrs. Tranchell.

CLASS F.—VEGETABLES:—English vegetables—general collection grown in Kandy or neighbourhood, 1st prize, gold medal, Mrs. Booth; 2nd prize, silver medal, A. Whyte; ditto, grown upcountry, 1st prize, gold medal, H. Young; 2nd prize, silver medal, W. H. Watson. Native vegetables, general collection, 1st prize, silver medal, Ratwatte Ratemahatmeya; 2nd prize, silver medal, B. Jayawardene; 3rd prize, bronze medal, Tumpane Ratemahatmeya. Pot-herbs, collection of, bronze medal, R. C. Tissera; Yams, collection of, bronze medal, A. Whyte.

CLASS G.—FRUIT:—General collection grown in Kandy or neighbourhood, 1st prize, gold medal, Mrs. R. Boustead; 2nd prize, silver medal, Paranatale; ditto grown upcountry; 2nd prize, silver medal, J. H. Silva; mangoes (6) six, silver medal, J. L. Dewar, J. H. Silva, extra prize; oranges, (12) twelve, silver medal, O. A. G. Perera; pineapples (3) three, silver medal, H. S. Daniel; plantains, collection of, silver medal, Harispattu R. M.; coconuts (6) six, silver medal, D. A. Jayawardene; pears, extra prize, Mrs. Ellis.

CLASS H.—NATIVE PRODUCTS (Grown by the exhibitor). Money prizes or medals given in this class at the option of the winners. General collection, 1st prize, gold medal, P. B. Dissanayaka; 2nd prize, silver medal or money, D. L. Wickramasekara; 3rd prize, Kobbekadua President; paddy, hatiyal, mawi, hondawala, hinati, balawi, elwi, ($\frac{1}{2}$ bushel of each sort), gold medal, P. B. Dissanayaka, 2nd prize, Puchi Rale; paddy, muttu-samba, kaivara sumba, sulai, or any of them ($\frac{1}{2}$ bushel of each or any), silver medal or money, no award; other grains, collection of, silver medal or money, Puchi Rale, Registrar; flour, arrowroot, tapioca, plaintain, &c., silver or money medal, A. Delwola; pulses, best collection of, silver or money medal, no award; spices.—Nutmegs, cloves, pepper—named, silver or money medal, Harrispatuwa R. M.; jaggery, silver medal or medal, no award; cotton (kapu) cleaned (56 lb.), 1st prize, gold medal, no award; 2nd prize, silver medal, no award; cocoa, (6 lb.), silver medal, L. B. Nugewela; tea (2 lb.), silver medal, Werapitia Arachchi; tobacco, (cured) 2 lb., silver medal, Palama-cumbure Lekama; gums and resins (with their names), silver medal, A. J. W. Marambe; drugs (with their names), silver medal, K. Puchirale; fibres, and ropes

(with their names), silver medal, no award; dye stuffs (named), silver medal, no award; woods (named), silver medal, J. F. Wijesekere; tanning materials, (named), silver medal, Arthur De Silva; agricultural implements, silver medal, Rambukwelle R. M.; seeds, silver medal, extra prize. Palle Mulle Veda.

CLASS J.—DAIRY PRODUCE, &c.:—Fresh butter (2lb), 1st prize, silver medal, Mrs. Booth; 2nd prize, silver medal, Mrs. Anderson; Best basket of 12 fowls' eggs, bronze medal, Mr. Joseph Fraser, Mrs. Booth; 2nd prize; Best basket of 12 duck eggs, bronze medal, H. J. Vollar; Fruits in syrup, silver medal, Mrs. Anderson; Best collection of jams and jellies, silver medal, Mrs. J. Anderson; Chutnies, bronze medal, P. Curpenah; Best 2 lb. loaf of home-made bread, silver medal, W. H. Dias Boar, silver medal, J. Hampton; Fowls (cock and two hens), pure breed, silver medal, J. Fraser; extra. C. J. R. Le Mesurier; Pigeons, bronze medal, W. Woth; Rabbits, bronze medal, Miss K. Anderson.

CLASS K.—ESTATE PRODUCTS:—General Collection, "from one Estate," 1st prize, gold medal, C. Gibbon, 2nd prize, silver medal, R. Boustead, Tea.—Set of samples of *bona fide* Commercial teas, broken pekoe, pekoe and pekoe souchong from the same estate (5 lb. of each grade) 1st prize, gold medal, A. E. Wright; 2nd prize, silver medal, E. G. Reeves; 3rd prize, bronze medal, G. F. Walker; Tea.—Set of samples of Fancy Teas, (2 lb.) each grade silver medal, Joseph Fraser; A. V. Renton, extra for Oolongs; Coffee, (56 lb.) and one bushel in parchment silver medal, W. Milne; Liberian Coffee (56 lb.) and one bushel in Parchment silver medal, W. Milne; Cacao (Commercial) 28 lb. 1st prize, gold medal, A. G. Imray; 2nd prize, silver medal, H. J. Vollar; Cardamoms, (5 lb.) 1st prize, silver medal, J. Fraser; 2nd prize, bronze medal, R. Andrews; Cinchona Bark, collection of silver medal, J. G. Macfarlane; Cinchona Officinalis, silver medal, F. G. A. Lane; Cinchona Succiruba, bronze medal, F. G. A. Lane; Tobacco, Marketable leaf (28 lb.), Gold medal, H. J. Vollar; Indiarubber, (5 lb.) silver medal, W. Milne; Vanilla, (2 lb.) silver medal, H. J. Vollar; Machine used in the manufacture of tea of a description not previously exhibited in the Colony, gold medal, James Westland, new tea machine.

CLASS L.—LIVE STOCK, &c.:—Ceylon-bred buffalo, 1st prize, gold medal, Gangawatta Koral; 2nd prize, silver medal, A. Nugawela R. M.; Native bull, gold medal, M. Ponnaswampulle; Native cow in milk, silver medal, Juwanis Appu; English or Australian bull, gold medal, H. J. Vollar; English cow in milk, silver medal, His Excellency the Governor.

CLASS M.—HORSES, DOGS, &c.:—Best hack, 14.2 and over, 1st, gold medal, Miss O'Grady, 2nd, silver medal, Miss Gordon; Best cob over 13.2 and under 14.2 hands, H. Bois, J. R. Jackson 2nd prize; Best pony 13.2 or under, De Chermont; Best country-bred mare or horse of any description, C. J. R. Le Mesurier.

DOGS.—Beagles, under 18 inches—to include beagle terriers—one couple, silver medal, G. J. Murray, extra F. Pulley; Terriers, (a) bull-terrier, silver medal, J. R. Jackson; (b) fox-terrier, silver medal, Mrs. Alexander; (c) fox-terrier, country-bred, silver medal, A. E. Flemming; (d) any other terrier, silver medal C. De Chand; Best native dog, five rupees, A. L. J. L. Marikar; Mastiff, silver medal, Mrs. Raie; House-dogs, (Colleys, St. Bernards), silver medal, J. Wickwar; Cat, 1st prize, silver medal, A. T. Karlake, 2nd prize, Miss O'Grady.

CLASS N.—SPORTING TROPHIES:—For the best pair buffalo horns, silver medal, C. J. R. Le Mesurier; For the best pair deer horns, silver medal, Mr. Hampton; For the best elephant's foot, silver medal, Major Morland; For the best collection of sporting trophies—1st prize, gold medal, O. J. R. Le Mesurier. The above exhibits were bagged by the Exhibitor. For the best collection of Ceylon skins and furs, silver medal, A. M. Jacob; For the best collection of stuffed birds, silver medal, A. Whyte; For the best stuffed trophy, silver medal, A. Whyte; For the best mounted head of any animal, silver medal, A. Whyte.

CLASS O.—ARTS AND MANUFACTURES:—Prizes in this class will be awarded only to the actual makers. Silver work, silver medal, Kiri Appu Mudirama; Brass work, silver medal, V. Veloo and M. K. Sino Nadei;

Mixed work, silver medal, H. Kiri Appu; Ivory work, silver medal, K. Art Work Association; Wood carving, silver medal, K. W. Don Abraham; Models, silver medal, Kobbekadua President; Drawings and paintings, silver medal Panchirala Registrar; Basket work, silver medal, Mangur Saibu; Mats, silver medal, H. Maha Duraya; Collection of products of coconut palm (name), silver medal, E. R. Tillakeratne; Painting (watercolours), silver medal, Willforce Haddon; Clock made in Ceylon by the exhibitor, silver medal, Frank Cramer. The clock made by Mr. F. Cramer of Kandy was much admired, as the workmanship of a native of Ceylon. The wheels, pinions, rivots, brass spring, pendulum &c., were all made by him. A special prize was therefore awarded. This is the first clock made in the island, and the exhibitor deserves all credit.

CEYLON TEA FUND.

Minutes of proceedings of a meeting of the Standing Committee of the "Ceylon Tea Fund" held at Kandy, on Saturday, the 25th day of May 1889, at eight o'clock (8 a. m.) in the morning.

Present:—Messrs. L. H. Kelly, Chairman, Planters' Association of Ceylon; A. T. Karslake, Kandy; G. A. Talbot, Chairman, Dimbula Association; Jas. H. Barber, Kandy; Hon. Thos. North Christie, Maskeliya and Kandy; Messrs. A. Melville White, Kelebokka and Kandy; Wm. Mackenzie, Kandy; O. S. Armstrong, Hewaheta; Dr. Duke, Kandy; T. C. Owen, Kandy; W. D. Gibbon, Kandy; D. Edwards, Kandy; and A. Philip, Secretary, Planters' Association of Ceylon.

The notice calling the meeting was read.

The minutes of proceedings of a meeting of the Standing Committee of the Ceylon Tea Fund held at Kandy, on Saturday, the 30th day of March 1889, were taken as read and confirmed.

Read letter from the Honorary Secretary, Dimbula Association. Resolved:—"That an abstract of the account of the 'Tea Fund' be prepared for publication as soon after the close of each period of six months as possible in addition to the annual report."

Read letter from Messrs. George Stuart & Co. with proposal regarding pushing Ceylon tea in the South of Ireland. Resolved:—"That a chest containing 50 one-lb. packets of Ceylon pekoe tea be sent to Mr. J. T. Sikes in response to his application through Messrs. George Stuart & Co."

PARIS UNIVERSAL EXHIBITION.

Read letters from Messrs. Wm. Martin Leake and J. L. Shand.

GLASGOW INTERNATIONAL EXHIBITION.

Read letters from Mr. J. L. Shand with statements of accounts.

BRUSSELS INTERNATIONAL EXHIBITION.

Read letters from Mr. J. L. Shand with statements of accounts.

Resolved:—(I) "That Mr. Leake's letter be acknowledged; (II) that the Committee notes the arrangement made with Messrs. Spiers & Pond, and feels sure that the Committee will specially see that the advertising of Pure Ceylon tea is thoroughly carried out; (III) that Mr. Leake be asked to consider the matter of appointing agencies in Paris for the sale of Ceylon tea, and to confer with Mr. Rutherford on the subject; (IV) that a further sum of twenty-five pounds (£25) sterling be placed at the disposal of the London Committee for any prosecutions advised under the Trades Marks Act."

Resolved:—(I) "That Mr. Shand's letters be acknowledged, and that he be thanked for all the trouble he has taken with regard to the Paris Exhibition, that the Committee is of opinion that, as a London Sub-Committee is now carrying out the arrangements connected with the Paris Exhibition, all correspondence had better come in future through the Secretary of that Committee; (II) that the statement of claim by the native servants employed at Glasgow and Brussels Exhibitions as given by D. Santiago in answer to memorandum of questions by the Secretary dated 13th May 1889 be

sent to Mr. J. L. Shand, and that he be informed that, if his account of amounts due the servants be not received within two months, the amount shown in the statement now forwarded to him will be paid."

MELBOURNE CENTENNIAL EXHIBITION.

Read letter from Mr. H. Mackenzie enclosing draft for £99 17s 2d, being value of 1,880 lb. of tea sent down for sale at the Ceylon Tea Court, and intimating that detailed accounts of expenditure would follow by an early mail. Resolved:—"That Mr. Mackenzie's letter with enclosure be acknowledged, and that his attention be drawn to his promise to forward by an early mail detailed accounts of expenditure."

CEYLON TEA IN NEW ZEALAND.

Read (I) letters from Mr. J. Fenton Wingate with reference to his free distribution of samples of Ceylon tea in New Zealand and transmitting a letter from the New Zealand Farmers' Co-operative Association with an order for some 4,575 lb. of similar Ceylon tea read (II) letters from Messrs. J. M. Robertson & Co., advising the purchase and shipment of tea in execution of this order value R3,015'17 as per invoice.

THE NEW ZEALAND AND SOUTH SEAS EXHIBITION 1890.

Read letters from Messrs. Kenneth S. Begg, Robert Andrews, J. F. Wingate, and S. Foulkes in reference to the representation of Ceylon tea at this Exhibition. Resolved:—(1) "That Mr. W. Watson, manager of the Colonial Bank of New Zealand at Dunedin, be communicated with and his good offices asked to endeavour to secure an efficient representation of Ceylon tea at the Exhibition; (2) that a sum of three hundred pounds (£300) sterling be voted for the New Zealand Exhibition."

CEYLON TEA IN GERMANY.

Submitted letter from Mr. M. Bremer giving details of Mr. H. Sixtus' plan for introducing Ceylon tea into Germany. Resolved:—"That the subject be referred to next meeting of the Standing Committee."

GRANT OF CEYLON TEA TO AUSTRO-HUNGARIAN LLOYD'S STEAM NAVIGATION COMPANY.

Read letter from Messrs. J. M. Robertson & Co. regarding the purchase and delivery of 5 boxes = 100 lb. Ceylon tea to the agent of the Austro-Hungarian Lloyd's Steam Navigation Company.

SHIPMENT OF CEYLON TEA PER MR. T. C. ANDERSON TO

THE ARGENTINE REPUBLIC.

Read letters from Mr. T. C. Anderson on the subject of the shipment of tea for free distribution in the cities of the Argentine Republic, and enclosing cheque for R261'86 in payment of tea. Resolved:—"That a copy of Mr. Anderson's letter be sent to Messrs. J. M. Robertson & Co. for their information."

CEYLON TEA IN SOUTH AUSTRALIA.

Submitted letters from Messrs. Drummond Brothers, Adelaide, South Australia, asking permission to represent the Planters' Association in South Australia, and to advertise the fact as a means of making Ceylon tea known in the colony. Resolved that consideration of this letter be postponed to a future meeting.

The CHAIRMAN read the following letter of acknowledgment of the Ceylon tea forwarded recently for presentment to Her Majesty the Queen:—

Windsor Castle, April 22nd

Dear Mr. Anderson,—I duly received your letter of the 19th, and the following day I laid the contents before the Queen, and I have now the pleasure of informing you that Her Majesty is happy to accept the parcel of tea sent by the Planters' Association Ceylon, and I am commanded to express Her Majesty's thanks which the Queen hopes you will convey to the gentlemen who have sent this offering. —Believe me with kind regards, yours very sincerely,

(Signed) S. ROXBURGH.

The Standing Committee of the "Tea Fund" then adjourned.

A. PHILIP,

Secy., Planters' Association of Ceylon.

IN TASMANIA: SOUTHWARD HO!

FRUITS AND OTHER INDUSTRIES—THE RABBIT PLAGUE—SCARCITY OF WATER AND THE AVERAGE ANNUAL RAINFALL—THE EUCALYPTUS AND OTHER VALUABLE TIMBERS—HOBART AND TASMANIAN SCENERY—ORNAMENTAL TREES AND FLOWERS—FISHES.

Hobart, May 7th, 1889.

The almost perpetual sunshine here (even when frost occurs at night the sun is often blazing hot by day) is so favourable to the production of fruit, that this enterprise is "going ahead" in Tasmania at the rate which tea is doing in Ceylon. On grafted trees two years from the nursery, say three to four years old in all, fruit is obtained from apple, pear, cherry, plum, apricot and peach trees, while gooseberries, raspberries and strawberries thrive equally well. Such apples and such loads of them (even yet) on mature trees I never saw, and apart from the opening trade with Europe, all the Australian Colonies consume vast quantities of fruit. But all is not gold. There are the drawbacks of scarce and dear labour, rendering it impossible for farmers to keep their gardens properly weeded; the rabbits, when they can obtain access to young orchards (and they sometimes burrow under net fences) ring and kill the apple trees, as the brown bugs used to treat our coffee trees. Then there is, in the case of apples, the codlin moth, for the repression of which all orchardists have to pay a tax of 2s per acre. There is a penalty on the selling of affected fruit, and so they and the very small apples (common this year in consequence of the dry season) are boiled and used as food for pigs. Small potatoes are used to feed fowls as well. The result of competition and large production of fruit has been that, according to my good friend Mr. Forsyth, the price of apples has gone down since 1856, from £1 per bushel to 3s. Still the pursuit seems to pay, this and farming when families are able to do most of their own work. Herein is the value of sons and daughters, to immigrants and settlers. Mr. Dale mentions Lord Dufferin's statement to this effect to an emigrant who sailed with him and who responded with "Right you are, sir; that's just what I've been telling Maggie!" But in new countries men must be ready to turn their hands to anything; and a very intelligent farmer and orchard owner, a Tasmanian born, who owns extensive possessions on the hill slopes which rise from the Derwent near Bridgewater, came in from gathering the "windfalls" in his orchard in order to go with us to his limestone quarry and well-built kiln, showing us also the jetty into the Derwent whence his own sailing boat starts frequently with loads of excellent hydraulic lime for Hobart. The formation generally along the Derwent is largely limestone, with drift gravel near the river. The yellowish colour of the limestone, I understood, and when I saw beautiful white marble-like blocks in the quarry fall, I never doubted that these, apparently pure carbonate of lime were chosen for burning. But no: the "blue stone" was selected in preference,—not the volcanic formation known by that name in Victoria, but bluish-grey limestone which burns white, and with which a good deal of marl is associated. "Free-stone," white and yellowish-brown, is abundant; and much of the beauty of Hobart, when the sun is reflected from the buildings (as it so frequently is), is due to the large employment of this material in the better class of houses and the handsome public edifices. Mr. Wilson, the farmer referred to born in Tasmania in 1820, complained, like all other owners of agricultural and pasture lands, of the ravages of the rabbits, which deprive the sheep and cattle of their food, eating the grasses and other plants, to uproot which they scratch the soil.

But he strongly objected to the remedy of phosphorized oats, the use of which, it seems, the Government at one time rendered compulsory. He told me that the insectivorous shrike, known as the "maggie," from its plumage, swallowed the poisoned oats and died in such numbers that grubs and grasshoppers increased to an injurious extent. As to families doing their own work in these colonies, it must be remembered that the climate enables the mother and daughters in well-to-do families to perform most of the household work and yet preserve the refinement and the accomplishments of ladies.—I was told that turnips for cattle feeding do not answer well here in consequence of the prevalence of "fly," but there is compensation in the splendid mangolds which are grown. Noticing no clover and hay fields, but green corn crops in the fields and straw stacked as hay, I learned on inquiry that clover and rye grass do well in normally moist seasons, but that two dry years had rendered their cultivation impossible and had compelled resort to green crops and the drying of them as substitutes for hay. In walking over farms and orchards, and in going up creeks, gullies and slopes on the hill ranges which rise from the banks of the Derwent, I was struck with the dryness of the surface and the paucity of waterholes, the water in such holes being brown with mud. I believe I have previously mentioned in the *Observer*, what I was told in Victoria, that horses bred on the "runs" get so accustomed to muddy water, that earth has to be stirred into the pure water, when it exists, put into troughs for horses at inns on the roadsides. Water for irrigation purposes would have been "worth its weight in gold" to the farmers and agriculturists along the sides of the Derwent in the past two dry years. The average annual rainfall of Hobart is only a little over 23 inches and in 1887 only 18 inches fell. Deep digging and the bringing of subterranean springs to the surface are the remedies, but capital and co-operation and machinery are necessary for this purpose. They will all be ultimately applied. I have been amazed at the enormous size of masses of timber lying on the wharves here, and although Hobart has been in existence since 1803 (six years subsequently to the establishment of the British in Colombo) there are still grand trees on the sides of the ranges which everywhere rise from the undulating basin and "foot-hills" amidst which the beautiful capital is situated. The prevalent eucalyptus is "peppermint," *E. amygdalina*, and the stems ragged with bark which the tree is casting off, or, more generally, gleaming white as polished marble, are very striking. This tree makes excellent firewood, the twigs, even when green, being good for lighting fires. Owners of timbered land who want it cleared for pastoral or agricultural purposes, allow the timber (in the neighbourhood of Bridgewater, 12 miles from Hobart, to be cut and carted away for 1s per cart-load. Those who have no such object in view, charge 6s a load for firewood. But good coal has been found in many places, and supplies of this mineral ("black diamonds") are likely to contribute largely to the wealth of this island, so highly favoured by nature in beauty and wealth. The climate, although it can be intensely cold at intervals (the heat of summer being much less than that experienced on the neighbouring Continent), is also, undoubtedly, salubrious to an exceptional degree. That is, if the ordinary laws of sanitation are observed. Had you accompanied us in our trip of five miles, up the lower ranges of Mount Wellington, to "the Bower," whence Hobart derives its water supply, you would have been struck as we were with the general resemblance of the hill and

mountain features to similar scenery in the higher mountain regions of Ceylon. The great difference is the paucity of streams here, such as tumble down our mountain sides in Ceylon. The eucalyptus, "wattle," thorny box, casuarina and cherry tree vegetation, was, of course, very different when seen close at hand, and even the tall tree-ferns which constitute "the Bower" and shade a long table placed for the convenience of picnic parties differed from ours, the divergence being entirely in favour of the lower but more gracefully curved branches and fronds of the Ceylon form. But I do not know that the balsams and *nitus* which form the chief undergrowth of our jungles must not yield the palm of beauty to the small flowering plants which carpet much of the dry forest floors here. For instance, there is the heath-like plant, with its lovely pink tubular blossoms, of which I enclose a specimen. There are no ericas in the flora of Tasmania, but this is an excellent substitute. It is known as "the red *Epacris* (*Epacris impressa*), and is finely figured in Mrs. Meredith's charming book "Tasmanian Friends and Foes: Feathered, Furred and Finned," the coloured pictures in which are produced in Marcus Ward's best style. Still more beautiful than the heath-like plant is the "Austrian fuchsia," which, however, is no more a fuchsia than the other is a heather. The native fuchsia is, botanically, *Correa speciosa*, and its drooping scarlet and gold flowers are truly lovely. Pretty also is "the native lilac," *Tetratheca glandulosa*, and the brown fruit of "the native pepper," *Tasmania aromatica*. In walking to and from "the Bower" we picked up, amongst the white daisies which looked very home-like, quite a number of "mountain berries," closely resembling some I have seen in Ceylon. Mrs. Meredith has given faithful portraits of this "purple berry," *Billardiera longiflora*, and of the lovely "white cluster," *Gualtheria hispida*, with its rose-like leaves and delicate white petals with red centres. The stems resemble those of a moss rose. "The blue berry," *Drymophila cyonacarpa*, is very pretty, and so are the red, white and black "native cherries" which show their stones outside the fruit, the only fruit of any mark indigenous to Australia. The botanical name is *Aristotelia peduncularis*. The pictures of curious-shaped and richly-coloured fishes in Mrs. Meredith's book are as faithful as those of the flowers and berries and the butterflies and mantises, green and brown (the latter a stick insect), which the artist represented as resting on them. The queerest fishes are "the butterfly lobster," *Hacrus pronii*; "the pig-faced lady," *Histiopterus recurvirostris*; and, strangest of all, the richly coloured but grotesquely absurd "superb dragon," *Phyllopterus julianus*. Fish is fairly plentiful and good here, and at Bridgewater I saw a fine bag of mullet which a boy got in a few hours by the side of the causeway and bridge over which road and railway cross the Derwent. This river is as famous as ever for its enormous salmon trout, but the existence of the true salmon in its waters is still considered "doubtful."

WEIGHT OF TEA: HOT AND COLD LEAVES.

A wellknown planter writes:—

"On trying an experiment it was found there was a difference between the weight of hot tea leaves and cold of 2½ per cent. As nearly every planter packs his tea hot after rearing, it may account for the loss of weight which takes place in England, but why it is not discovered in Colombo puzzles me. Anyway the matter is worth enquiring into."

The Planters' Association, through Mr. W. Martin

Leake, on one occasion instituted careful inquiries in regard to the weight of parchment coffee per bushel, and settled that question finally. It would be well if similar experiments were made by the P. A. Committee to settle the above and other points about tea.

BARK AND DRUG TRADE REPORT.

LONDON, May 9th.

In our last issue we reported the sale of some ANNATTO seeds, at Thursday's drug sales, at 2d per lb. The accuracy of this report is denied by a firm of Mincing Lane brokers, who claim that the seeds were bought in at 4d per lb, though they might have been had at 2d per lb. These brokers say that they had an order for annatto seeds from a large provincial customer and executed it at 2½d per lb, to which price their client upon reading THE CHEMIST AND DRUGGIST'S report, demurred. Now we have referred to our own catalogues of the auctions, and also to the printed lists of three different firms occupying different positions in the room. They all say that the seeds were sold at 2d per lb. But the broker who offered the seed denies having sold them. The inference, therefore, is that if the seeds were not actually sold the lots were treated in such a way by the presiding broker as to lead different observers, all presumably alive to what was going on, into the belief that a sale was made. When we pointed this out, we were told that brokers often do their best to mislead the room and to keep their prices secret. Possibly this is so, but the question is whether that game is worth the candle, or whether such an action is calculated to injure those who have recourse to it most of all.

CINCHONA.—The public auctions on Tuesday were, as might have been expected, extremely heavy. They comprised of:—

	Packages	Packages
Ceylon bark	2,098	of which 1,691 were sold
East Indian bark	1,623	" 1,257 "
Java bark	170	" 170 "
South American bark	55	" 30 "
Total	3,946	" 3,148 "

East Indian barks, from the Wynaad and Mysore districts, were again largely represented, and the quality of these barks was generally good, several parcels bringing prices which pointed to a sulphate of quinine equivalent of 4 to 6 per cent, and for such parcels there was a good competition at full rates. The Ceylon barks, however, included a very large proportion of poor stuff. At the commencement of the auctions there appeared to be a very fair demand, but gradually this fell off, and towards the close of the sales only very low figures could be obtained, and some brokers bought in a rather larger proportion of their goods. The unit is generally placed slightly lower than at the preceding auctions, though fully as high as the average of the Amsterdam sales on May 2d.

The following are the approximate quantities purchased by the principal buyers:—

	Lb.
Agents for the Auerbach works	200,267
Agents for the American, French, &c., works	148,081
Agents for the Brunswick works	136,581
Agents for the Frankfort o/M and Stuttgart works	110,057
Agents for the Mannheim & Amsterdam works	87,550
Messrs. Howards & Sons	20,555
Mr. Thomas Whiffen	4,300
Sundry druggists...	62,857
Total sold	770,645
Bought in or withdrawn	188,944

Total quantity catalogued ... 959,592

It should be well understood that the mere weight of bark purchased affords no guide whatever to the quinine yield represented by it, firms who buy a small quantity of bark by weight frequently taking the richest lots, and *vice versa*. An analysis of the catalogues gives the following prices for sound bark:—

CYLON BARK.—Original.—Yellow varieties: Spoke chavings, fair to good 2d to 3½d; richer ditto mixed with chips up to 5d; chips, ordinary to good fair 1½d to 4½d; good to rich chips mixed with quill, 4d to 8d; root, 5½d to 6½d. Red varieties: Thin dull to good chips, 1½d to 3d; mixed with twigs, 1½d to 3½d; shavings, 3d to 4½d; ordinary dusty to good root, 2½d to 4d. Grey and hybrid varieties: Fair to good chips and shavings, 3d to 4d per lb. Renewed.—Yellow varieties: Ordinary to good stem chips, 3d to 5½d; chips and shavings up to 6d. Red varieties: For chips and shavings an offer of ¾d per lb. was refused; ordinary to fair chips, 2d to 3½d; chips and shavings, 4d to 5½d. Grey: chips 2½d per lb.

EAST INDIAN BARK.—Original.—Yellow varieties: Small to fair chips, up to 3½d; fair to fine chips mixed with shavings, 4d to 7d; fine shavings, 9d; fair but broken to good druggists' quill, 5½d to 8½d. Red varieties: Fair chips, 3½d to 4d; twigs, 1½d; root 3d to 3½d; fair to good bright spoke shavings, 2½d to 4d; druggists' quill, ordinary broken and papery, 3d; fine old. 9d; and very fine heavy old, up to 1s 4d per lb. Renewed.—Yellow chips: 6½d to 7d; grey chips, 6d to 7d; red chips, 5d to 7½d; hybrid, 5½d per lb.

JAVA BARK.—Grey: Fine chips, 6d to 6½d; fair chips, 3d to 3½d; common twigs, 1d to 1½d; root, 4d to 6d per lb.

SOUTH AMERICAN BARK.—Of 45 packages cultivated Bolivian Calisaya, 28 were sold at 7d to 8d for good short partly silvery quill. Eight cases bold, but very dark and damaged, Carthagea are held at 9d per lb. For two bales so-called Red bark, imported via Hamburg, very ordinary colourless quality. 9d was paid for sound, and 2½d for damaged. The shipments of bark from Colombo in the periods between October 1st and April 11th have been:—

1888-9.	1887-8.	1886-7.	1885-6.
lb.	lb.	lb.	lb.
6,490,357	5,803,395	8,081,374	7,929,889

The following figures are taken from the official commercial returns for April:—

	1887.	1888.	1889.
	cwt.	cwt.	cwt.
Imports, April ...	13,375	10,724	15,869
„ Jan. 1—April 30	57,612	47,331	61,077
Exports, April ...	14,950	10,025	9,569
„ Jan. 1—April 30	54,747	40,031	43,845

At the Amsterdam auctions on May 3rd the bark offered contained an equivalent of about 240,000 oz of quinine sulphate. The results of the chemical analyses were widely different, especially for manufacturing barks, and the prices paid fluctuated a good deal. Druggists' barks in long stout quills met a good demand, and a few cases of fine quality realised comparatively high prices. The richest lots were 6 packages Ledger original stem chips; 8·37 per cent. Q. S. sold at 62 cents, 8 packages ditto renewed stem chips; 8·17 per cent Q. S. sold at 64 cents, and 13 packages ledger broken quill; 8·92 per cent Q. S. sold at 59 to 60 cents. The principal buyers, in order of their purchases, were:—

	Kilos.	Kilos.
	Bark	S. Quinine
The Mannheim and Amsterdam Factories ...	41,820	1,371
The Auerbach Factory ...	38,425	1,240
Agents for the American, French, &c., Works ...	47,988	1,180
The Brunswick Factory ...	14,500	662
The Frankfort o/M. and Stuttgart Factories ...	10,300	640
M. Paillender, Paris ...	4,488	315
Various other Manufacturers ...	10,081	198
Druggists ...	8,278	...

COCA LEAVES.—On Friday 4 cases (24 lb each) of very fine bright green leaves, grown on the Kelvin estate in Ceylon, were disposed of at auction at 1s 10d per lb., an exceptional price. There have been sundry small shipments from Ceylon during the last few years, but this we think is the heaviest one ever received, though the article has now been cultivated in the island for a good many years. Some five or six years ago, during the rush for coca leaves, owing to

the discovery of the anæsthetic properties of cocaine a parcel of Ceylon leaves realised the highest price ever known for the drug. Twenty-five boxes (16 lb each) Java leaves were all sold on Friday, good green, but broken; leaf, at 6d per lb.; brown at 3d per lb.

CUBEBES.—Of 12 bags stalky berries, mixed colours and sizes, a few damaged ones sold at 22l to 22l 10s per cwt. We hear from Amsterdam that 195 piculs of new crop cubeb berries are on the way for that port from Java. The latest reports from the island confirm the rumour that the crop has been a small one, and owners are firm at the high quotations of the previous season.

QUININE.—This article has been weak since our last report. On Friday last 1,000 oz. in large bulk B. & S. quinine sold at 1s 0½d per oz. at auction, and since then there have been second-hand sellers at that price, and later in the week at 1s 0½d. Today we hear it reported that 5,000 oz. have sold on the spot at 1s 0½d per oz. The speculative German brands are quoted by the manufacturers at 1s 2d per oz.; Italian at 1s 1½d per oz.

VANILLA.—Several parcels have arrived from Ceylon lately. In the Mauritius market, on April 10th, vanilla was scarce, and fine long beans were not to be had.

ESSENTIAL OILS.—At auction 100 cases Citronella oil sold without reserve at 3d per oz. Large quantities of this oil continue to be exported from Ceylon in addition to the produce of other sources. Of Cinnamon bark and leaf oils the export from Ceylon have thus far been very small this season.—*Chemist and Druggist.*

A TOBACCO BOOM.

People are beginning to talk and to speculate on a tobacco boom, which is to altogether put the recent Pahang flutter into the shade. Matters certainly seem shaping that way, and the prices realised at Amsterdam for the first arrivals of the 1888 Sumatra crop are certainly high, and tend to increase the belief. A recent report by Messrs. Van Prehn & Co., bankers, of the Hague, upon the market for Sumatra tobacco, and for tobacco companies shares, states as follows:—

The shares of the different leading Dutch Deli and Langkat Tobacco companies have undergone, during the last three weeks, a sudden and tremendous rise. The official lists of the quotations on the Amsterdam Stock Exchange show that the shares of the Amsterdam Deli Company stood at 360 per cent. on the 2nd inst., and are now at 451 per cent. The shares of the Arendsburg Tobacco Company, which stood at 800 per cent. on the 2nd instant, are now quoted at 836 per cent. The shares of the Deli-Batavia Tobacco Company which stood at 345 per cent. on the 2nd instant, are now at 429 per cent. The share of the Deli Company, which were at 520 per cent. on the 2nd instant, stand now at 610 per cent. The rise has been very sudden, and has taken place in leaps of from 5 to 15 per cent. per day. The reasons for this really astonishing rise are:—(1) The high prices at which the first cargoes of the Deli tobacco from the 1888 crop were sold at public auction in Amsterdam (155 cents, or 2s 7d, per lb.) (2) The rumours which have now become a certainty, that the 1888 crop, which will be sold in Amsterdam within the next six months, is a very good one; that the quantities of tobacco yielded by the different estates are very large, and that the quality leaves nothing to be desired, so that very high prices may be expected for the tobacco which has not yet arrived. (3) That the prospects of the 1889 crop, now planted, equally promise to be very satisfactory. It is generally believed here that the rise will continue, and that the shares of the Deli tobacco companies will attain a still higher figure.

Commenting on these facts the *Financial News* writes:—The Deli and Langkat Tobacco Company has several features not possessed by some of the tobacco companies recently launched, inasmuch as it is not an experimental venture, but the enlargement of a going concern. There is virgin land to be brought under cultivation, but there are also rich fields in full bearing, which yield an ample revenue, and have done

so for many years past. In reading over the statements of the prospectus, it would seem that the directors show rather too much modesty, and under estimate, rather than over-estimate, the present position of the estimates. For example, they look for a net profit of £35,784 upon the crop of 1888, now in course of shipment; but they take no account of the fact we have dwelt upon, that, partly owing to the superior quality of the 1888 crop, the Amsterdam tobacco market has had a very sharp advance over the figures quoted in the prospectus. This £35,784 ought thus to turn out not less than £50,000, which is a pretty good start. Again, they hardly lay sufficient stress upon the point that for the 1889 crop nearly a third more ground is being prepared, and it would not have been out of place to frame some estimate of what this increased acreage would return. It is always well, however, to be on the safe side, and the very modest way in which the case is put inspires confidence that all the estimates will be exceeded. The Deli and Langkat Company is very different from, and offers a much safer and probably more lucrative investment than, some of the Borneo companies, which may have to buy their experience, and buy it dearly.—*L. & C. Express*, May 10th.

"OOLONGS" AND "CONGOU" TEAS.—We call attention to the cheery letter of "Sabaragamuwa" with its practical advice to his brother planters about turning out a *proportion* of Oolongs and even of Congou tea. As regards a "proportion" we give our hearty support to the proposal and would only suggest to "Sabaragamuwa" now to give a few plain instructions for the benefit of his brethren in respect of Oolongs' preparation.

COFFEE ADULTERATION.—It would have been observed from the discussion in Parliament we reproduced yesterday, that Mr. Labouchere—of all men—is interesting himself in this question. The hon'ble gentleman was referred by Mr. Goschen to the President of the Board of Trade, Sir Michael Beach. If the Editor of *Truth* were to commence a crusade in his columns against "coffee adulteration," there would be some hope of reform, for difficulties have never been raised on the Conservative but on the Liberal side, as regards the introduction of anti-adulteration regulations for coffee and other food products.

BIG OR MEDIUM BREAKS OF TEA: MORE MYSTERIES OF THE TRADE.—We did think that if there was one thing more than another clearly settled, it was that the bigger the breaks of tea sent forward from Ceylon to Mincing Lane, the better for the planters—that big breaks were certain to be fully competed for, while the smaller ones were liable to be neglected. But we have lately had two cases mentioned in our presence, in one of which the accepted idea certainly receives a rude shock. A recent mail brought a complaint from a London proprietor of two shipments of his tea made rather closely together, not having been dealt with on this side as one, so securing a really good big "break" and probably a better price. In the other instance, an estate Manager lately received instructions in quite an opposite direction: his last shipment formed too large a break and in future the London agents would prefer to have a similar quantity divided into two breaks, as likely to secure competition from a larger number of buyers. Now which is right of these London proprietors or agents of estates? Perhaps there is a limit beyond which it is not safe to go as shutting out competition. What indeed may be said to be the limits both minimum and maximum, and what would be considered in Mincing Lane as the model break of Ceylon tea, securing the greatest amount of competition, are questions it might be useful to have answered at this time.

TEA IN GLASGOW.—It would appear that Mr. T. J. Lipton, the well-known provision merchant, intends making a new departure, as on Thursday 33 heavily laden lorries with boxes of tea were driven through the chief thoroughfares of Glasgow. The tea was labelled "for Lipton, from the tea gardens."—*Home paper*.

A VERY *chota* profit was made last year by the Chota Nagpore Tea Co. It plucked 52,396 lb. of tea, and sold it at a price that averaged an advance of 5½ annas on the price realised in 1887, and it reduced working expenditure, yet, "it has only just been possible to make the income cover the outlay, and the surplus on the season was only R12.0 3."—*Madras Mail*, May 20th.

NEW AND OLD PRODUCTS.—Though Mr. Holloway does not give a very cheering account of his experience in cotton, it is satisfactory to see that he has by no means lost faith in new as well as old products. As for the cotton sample he sends, it seems to consist a good deal of kapok (the tree cotton only useful for stuffing), but can this appearance be due to the damage sustained? The rest appears to be from the "kapu," otherwise called Kidney or Peruvian tree, and is of good quality and colour, valued at 20 cents per lb. and upwards.

TEA IN FRANCE.—An extract given elsewhere goes to show that the Consumption of Tea in France, though still a very small factor comparatively, has of late years, been steadily increasing. Messrs. Gow, Wilson & Stanton only showed about 500,000 lb. of tea as exported from Great Britain to France, the total consumption per head being given at 0.03 lb., or about 1,140,000 lb.; and to this approximate very closely the figures given by the authority under notice, the kilogram being taken at 2 1-5th not at 2 lb. as the *H. & C. Mail* has it. Let us hope as one result of the Paris Exhibition and other efforts now making, that France may henceforward go on doubling her consumption every year!

THE BUDGET AND COFFEE AND TEA.—Says an editorial writer in the very cleverly conducted new journal, the *Scots Observer*, in reviewing Mr. Goschen's Budget:—

There is always a certain charm about the most prosaic Budget. It throws a searching light upon the tendency of social habits. Mr. Goschen does not forget the human interest of his figures. He complains bitterly of the stationary quality of coffee. It may be suggested with all humility, as one reason of this, that but few people know how to make coffee, or indeed, will take any trouble to have it fresh and good. No wonder the reputation of coffee suffers, when it is identified with the sickening black mixtures which are served up in this land 'of sixty religions and only one sauce.' So also with tea: the revenue from tea is sluggish. It is our duty to hope it may remain so, while tea is a decoction of tannic acid which is as bad for society as 'blue ruin' or Zola's novels. It may also be suggested that a few prosecutions for the adulteration of tea might have a wholesome effect on the revenue. Again, Mr. Goschen seeks to explain the falling-off in wines by the use of the harmless necessary cigarette immediately after dinner. This is scarcely consistent with the disappointing character of the duty on tobacco, although the Chancellor professes to have discovered the introduction of a weed which takes much longer to smoke, and therefore produces less to the revenue. There is no doubt an extraordinary decline in the drinking power of the United Kingdom. If it is necessary in the interests of the revenue to remove all obstacles to free drinking, why not have a little simple Bill to permit A to prevent B from having a cigarette? The one idea is just as reasonable as the other.

We must send the editor a little information about the properties of Ceylon teas and how by proper infusion the tannin may be dispensed with.

TEA PROSPECTS.

We are pleased to learn that telegraphic intelligence from "the Lane" this forenoon is of a more reassuring character, reporting slightly better prices, while the opinion is current that we may have perhaps touched the lowest rates for Ceylon teas for some weeks at least. The relative cheapness of our teas this season, however, is likely to prove a blessing in disguise to the producers if, both in the United Kingdom and throughout Australasia, it lead to the mass of consumers getting supplies of really pure Ceylon teas. For, although, in the mother-country especially, the number of Ceylon Agencies has been multiplied exceedingly, while the Adulteration Act has deterred many of the first-class blending Houses from mixing the teas of different countries; yet there is no doubt a large quantity still of very inferior stuff palmed off as Ceylon tea that never came from this island. Assam and China imports chiefly make up such blends with a very little of Ceylon tea added. In one case we are told of a distributing company which has been sending out four or five tons a week of such teas and they are sold under most glowing descriptions as 'aromatic' (from the 'lovely island' of spices doubtless!), as luscious and yet as suited to weak digestions. Now, it is very certain that the comparative cheapness of sound, pure Ceylon teas will greatly affect this blending business and lead to the English (and we trust Australian) public being supplied much more freely with the real article at the prices they have hitherto paid for inferior blends. Again, with our Pekoe Souchongs falling to about 7d, we might expect China buyers to be very chary at this critical time, of indulging in business with a free hand. The relative cheapness of our teas ought to act as a "sore discouragement" of investment in the millions of lb. of China tea which are now doubtless offering at the shipping ports. It is too soon, however, to judge of this.

In the face of the good reports on the bulk of Ceylon teas arriving home, recently recorded, it is somewhat surprising to receive such a note as the following from a London-Ceylon resident (not in tea however):—

"Some years ago I wrote very strongly about inferior teas and suggested using them as fuel for driers rather than sending to London. The 'Ed. C. O.' said I was sarcastic, but I am sorry my forecasts as to prices were not far wrong. I hope better prices may soon be got, but the quantity you are sending is enormous." But has our friend fault to find with the quality of the bulk of our teas? Let him look at the brokers' reports for several weekly mails up to 10th May. Nevertheless we are free to admit that from the want of adequate accommodation, especially in withering room, and sufficient machinery, there is the real danger on many estates which may get a rush of leaf, of the poor Superintendent, do what he may, being unable to turn out a decent tea. What is a planter to do in wet weather with leaf covering his withering shelves two, three or four times the proper depth and no other provision available? So in respect of inadequate means of rolling and drying. We trust as one result of the check in prices, to see greater readiness on the part of those responsible for adjacent plantations, to try and coalesce so as to have one thoroughly well-equipped convenient factory for three or four estates. The money frittered away in trying in vain to do justice to each separately would probably more than suffice for one central adequate factory.

One further point has reference to the extent to which tea brokers and dealers not only in

Melbourne and Sydney but in London, are interested in the maintenance of the China tea trade. Again, the extent to which gentlemen of the Lane and large tea dealers generally, figure as shareholders and directors in Indian Tea Companies has been made the subject of remark. No doubt there are vested interests of a very important character not likely to view with favour the steady advance in consumption of our teas, but we have no fear of justice not being done to all produce on its merits in the Mining Lane public auction rooms, and none whatever of Ceylon tea not holding its own against all-comers in the keen competitive race which may now be said to be fully developed.

AN ENGLISH RUBY COMPANY FOR BURMA —WHY NOT A LONDON GEM COMPANY

FOR CEYLON?—No. III.

MR. STREETER'S MONOPOLY OF THE BURMA RUBY MINE:—REGULATIONS FOR AUCTION SALE OF RUBIES—THE GEMMING DISTRICT OF BURMA—PROSPECTS OF A GEM INDUSTRY IN CEYLON.

When discussing the possibility of developing the mining resources of Ceylon and contrasting the claims for support of a Company for that purpose with those of the recently formed Burma Ruby Mine Company, those who oppose the former lay very great stress upon the "solid advantage" the latter possesses in having "obtained a guaranteed monopoly of the produce of the ruby mines."

Considerable misapprehension appears to have arisen in regard to this "monopoly" which has been granted to Messrs. Streeter by the Indian Government. The general reading of the term monopoly in this concession seems to be, the sole and exclusive right to search for rubies in Upper Burma—thus barring all other persons and Companies from doing so. Nothing however, could be more erroneous than this idea—nor could any other reading of the term be possibly more misleading to the public.

The ruby mine district as marked upon the Government plans, is a very small part of the country, covering an area of about sixty square miles, which the King of Mandalay reserved for his own use, and over which the British Government, in assuming King Theebaw's throne and rights, holds the same reservation. Of this little district a moiety has been conceded to Streeter for a term of years. But the monopoly of that thirty square miles is not a monopoly signifying that Mr. Streeter alone and the Company's employees have the exclusive right to search for gems over the whole district. A little consideration will surely be sufficient to shew that no ordinarily constituted Company could possibly undertake to thoroughly turn over thirty square miles of country, delving to depths of 30—50—even 100 feet and examining every cubic foot of soil as will have to be done when the Company gets to work. From an engineering point of view such an operation is by no means an impossibility, but so gigantic an undertaking would have to be taken in hand by a colossal Company something on the scale of that of the Panama Canal. Messrs. Streeter entertain no such wild ideas, but have sent up washing machinery with which no doubt a very considerable amount of work will be done during the term of the so-called monopoly. But other parties are allowed to work in the ruby mine district, on condition that all the rubies they find are to be offered for sale to Mr. Streeter's agent, who, if he elects to do so makes an offer for them. Should this offer be accepted—the transaction is closed by the Government taking one-third of the purchase

money, and Mr. Streeter finds himself in possession of the gems for which he has paid the current market value. But in case Mr. Streeter's agent does not elect to make any offer, or in case the offer he makes for the gems is deemed unsatisfactory by the seller, they are handed over to the local authorities for auction sale, at which the agent has a right to bid like any other person. This then is the nature of the much-vaunted guaranteed monopoly. Mr. Streeter, no doubt in consideration for the sum paid for the concession, has a right to all gems he mines for himself, but has to pay for all other stones found in the ruby mine district, and pay too the highest current rate in the local market. Lest there should any doubt arise as to this reading of the term, monopoly here is an advertisement, one of a regular series, appearing in the *Mandalay Herald* of 27th April last, after the mining machinery had gone forward from Mandalay:—

AUCTION SALE OF RUBIES.

An auction sale of Rubies will be held at the Ruby Mart (Mandalay Treasury) on Saturday the 18th May 1889, at 1 p.m.

The stones which consists of rough stones from the Ruby Mines and stones rough and cut which have been confiscated under the Ruby Regulation, will be put up to auction in 114 separate lots, more or less, on which have been fixed upset prices aggregating about R20,600. A duty of 30 per cent ad valorem, is payable on purchase.

The sale will be conducted under the provisions of the Ruby Regulation, published in the Burma Gazette of the 1st October 1887.

A copy of the Ruby Regulation Rules, in English and Burmese, will be furnished to intending purchasers on application at the office of the Deputy Commissioner, Mandalay.

By rule 14 a license is required to buy and sell rubies, and by rule 13, only the holder of such license can buy stones at the Ruby Mart.

Such license will run for one year from the date of issue: the fee payable being R10.

Applications for licenses should be made on a Court Fee Stamp of eight annas to the Deputy Commissioner, Mandalay, from whom all further information can be obtained.

The rubies will be exhibited at the Treasury on Saturdays between the hours of 1 and 3 p.m.

C. B. COOKE, Major, Deputy Commissioner.

Mandalay, 16th April 1889.

It will be here seen that the 114 separate lots of rubies exposed for sale are "rough stones from the ruby mines," and stones rough and cut which have been confiscated under the Ruby Regulation, and for the purchase of these gems Mr. Streeter stands in no better position than if no such thing as a monopoly had been conceded him. So much for the monopoly of which such capital has been made, and which obtains only in respect to a small dot, as it were, on the immense gem-producing area of Upper Burma, an area comprising thousands and thousands of square miles, over which the Government do not pretend even to have a claim any more than King Theebaw had. Over this immense gem-producing country there is room for innumerable Companies and private parties who, making their own arrangements with the native chiefs and land owners, will probably stand on a better footing than Streeter's Company and its guaranteed monopoly. As a proof of the Government having no claim on the lands of the native chiefs may be adduced the fact that the present line of road to the ruby mines was made by special arrangement with a native headman, the tract of country through which the road runs having been given in exchange for another, and about which there is now considerable irritation, as the Government have discovered they have taken the least convenient route and wish to resume possession of what had been given in exchange.

Perhaps it may be urged that these statements in reference to a large gem-producing area are not supported by corroborative testimony, and the question may be asked from what source comes the information from which they are made. Apart from the general testimony of the residents

of the country, special opportunity was afforded by the company and friendship of a well-known European, whose residence of over 30 years' duration in India and Burma has been devoted to the trade in gems, and who accompanied by two Indian native experts has lately made it his business to obtain a thorough insight into the jewel resources of Upper Burma. Introduction was thus afforded to other sources of information amongst influential and intelligent natives, whose lives had been spent in the country and who were conversant with the doings of the late king. Besides these there was available information from the Europeans (Italians principally) who were in the service of Theebaw. In addition to all this, practical proof was afforded when joining a party of Europeans in some petty trading transactions at a small settlement of the Hill Shan tribes—some three hundred miles away from the ruby mine district. When the confidence of these hillmen had in some measure been secured, inquiry was quietly made for rubies. In the course of two or three days such a number of these gems were offered for sale as would make anyone who had invested deeply in Mr. Streeter's Company open his eyes with astonishment and dismay. Rough of course most of them were, many imperfect, and some probably set up with an artificial backing of colour, but rubies and sapphires they were—according to the experts of the party—and many of them of considerable size. There can exist no reasonable doubt that there is a vast tract of gem bearing country in Upper Burma and probably in Lower Burma also, and the sole advantage—if such it prove—gained by Mr. Streeter's Company is the protection of the British Government in a locality where the industry has already been carried on for some years past. With this exception any other Company, or any private party, has an equal chance of success with the famous Burma Ruby Mining Company.

It is said no such monopoly can be obtained from the Government of Ceylon, and in reply no such monopoly is wanted—nor cared for, nor would it be of any advantage if it could be obtained. If any particular tract of Crown land should be considered desirable it can be applied for and purchased in the usual way, but there are thousands of acres of gem land in the hands of private individuals, both European and native, for which absolute purchase could be arranged, or for which leases could be obtained; and in the gemming districts there are immense properties belonging to Buddhist and Dewala temples, which the present holders would be eager to lease for a lengthened term of years. What then would be the advantage of a Government guaranteed monopoly in Ceylon? Another objection put forward to the formation of a Company for Ceylon is that "the results to the existing industry are very variable and greatly dependent for success or otherwise on mere luck." This is an objection that holds good in almost every mining venture in the world, but affects such an industry in Ceylon less probably than in any other country. True it is that the existing industry must necessarily be uncertain in its results—as it merely consists in pricking little holes in the surface of the land just as fancy dictates. But knowing the results of such desultory search—we may form some definite idea of what may be done by systematic mining and washing after the land has been thoroughly prospected by competent persons, thereby making assurances doubly sure. Still another objection put forward is, "past experience shows" that gems were sold in Ceylon as the rule at about the prices—certainly not much below their current value in the London market. Without waiting to question the correctness of this assertion,—it may be pointed out that a local market is always the grand desideratum by

producers of every article of commerce. If the gems can be sold on the spot for the equivalent of their value in London it would be very advantageous indeed for the Company, and add immensely to the profits of the concern. It would be difficult to conceive anything which could be less of an objection than this idea of prices obtainable on the spot, equalling those in London. Again costly European supervision would have to be exercised over the miners working in detached pits, "there can be no mining in the ordinary acceptance of the term such as could admit of the workmen being closely observed and searched as they left work." Perhaps this is the most extraordinary of all the absurd reasons given why a Company should not be formed for Ceylon. There is no imaginable reason why "there can be no mining in Ceylon in the ordinary acceptance of the term." Surely the writer is not serious in thus insinuating the deduction that a Company would be content to go pricking little holes here and there in the surface of the country and imitating the natives in their petty endeavours to find a royal road to fortune. No man in his sober senses could suppose that any Company of Europeans would be content to operate on such a petty scale. "Mining in the ordinary acceptance of the term" would be the object of such a Company and the whole bulk of gem bearing land would be turned over and washed and made to yield the whole of its store of precious stones, which would be dealt with locally or in the European markets accordingly as circumstances dictated. The supposition of a Company imitating the existing mode of native working is too absurd to merit further comment.

The final objection made by the writer (whose remarks are under comment) only serves to show how entirely ignorant of the country he must be. He says: "Gems in Ceylon are not found in particular veins admitting of organized working. The precious stones of that island are various in character and are scattered in a very diffused manner, so that no parallel could be established between the ruby yielding *strata* of Burma and the gem pits of Ceylon." Now, as a matter of fact, there are well-known and well-defined gem producing *strata* in the gemming districts of Ceylon,—*strata* into which all these "detached pits are sunk," and which it has been ascertained in many places run high up over the hills at great distances from any stream bed of the present day. It would have been quite correct had it been asserted that in addition to well-defined *strata* producing gems—there are numerous precious stones scattered in a very diffused manner over a very great portion of the island. To those who are at all conversant with gemming operations in the island,—these *strata* are well-known as "Illan,"—and for those whose lot has precluded a practical acquaintance with the subject, the work entitled "Gold, Gems, and Pearls, in Ceylon and Southern India," will afford a very great deal of useful information.

By way of establishing a parallel between the ruby-yielding *strata* of Burma and Ceylon: Emerson Tennent's "Ceylon" has the following statement:—"The most remarkable of these gem-bearing deposits is the flat country round Balangoda, south-east of Ratnapura; but almost every valley in communication with the rocks of the higher ranges contains stones of more or less value, and the beds of the rivers flowing southward from the mountain chain are so rich in comminuted fragments of rubies, sapphires, and garnets, that their sands in some places are used by lapidaries in polishing the softer stones, and in sawing the elephants' grinders into plates."

Mr. Baker (now Sir Samuel Baker) thus describes

the sands of the Menikganga (jewel-river) near the ruins of Magama in the south-eastern extremity of the island:—"The sand was composed of mica, quartz, sapphire, ruby, and jacinthe; but the large proportion of ruby sand was so extraordinary that it seemed to rival Sinbad's story of the vale of gems. The whole of this was valueless, but the appearance of the sand was very inviting, as the shallow stream in rippling over it magnified the tiny gems into stones of some magnitude. I passed an hour in vainly searching for a ruby worth collecting, but the largest did not exceed the size of a mustard seed."

Now perhaps it will be said "this surely goes against the argument that gems of value are found in abundance in Ceylon;" yet "Mr. Streeter in denying the adverse criticisms passed upon the ruby mines venture, says as an example of the productiveness of the property, a ton of gravel which recently arrive in England from the mines, produced 1,800 carats of rubies, valued from a farthing each upward." This may mean a great deal,—or it may mean next to nothing at all. If it means a great deal we may be sure a very great deal more would have been said about it, and the enormous value of the outturn commented upon in glowing terms. But as the statement now stands, without further explanation, it really has no meaning whatever, no useful or definite deduction can be drawn from it, at any rate by the uninitiated in such matters. If any large proportion of this ruby gravel from Burma is now worth only a miserable *farthing each*, it is evident a very few more tons of it will reduce its value to that of the *valueless* ruby sand of the Menikganga. It may very reasonably be deduced that if such an evasive statement—as quoted above—is put forward by way of proof of the productiveness of the ruby mines, there must in reality be an alarming absence of some more tangible and convincing proof such as the shareholders are now beginning to demand.

Some of the objections to which allusion has been made are really almost puerile, and if nothing more solid can be urged in opposition to a Company such as is proposed for Ceylon, there should be no difficulty whatever in its formation, nor is there reason to doubt that one or more of such ventures will be put before the public before the year has gone by—ventures which contain every possible element of success.

LOCAL BUILDING MATERIAL:—TILES: A NEW INDUSTRY IN ITALIAN TILES?

We all recollect the agonies of Mr. John Briggs, so graphically depicted by the inimitable John Leech in his series of 'Domestic Miseries' which appeared in *Punch*, over the 'loose slate,' but it may well be doubted if the troubles of that representative British householder could be weightier than those of the resident of Ceylon who may be unhappy enough during the height of the monsoon rains to find that the crows in their gambols, or any other of many possible causes, have produced a broken tile on the roof of his residence. Even the army of artificers and labourers, with their giant ladders and other gear, which figure in John Leech's sketch, can hardly surpass in capacity for annoyance and for the creation of dirt the coolies who, owing to the peculiar method in vogue among us of covering in our bungalows, have to remove a hundred or more of tiles to come to the single offending individual among them; and it is because he has a keen personal sense of the gravity of such annoyance and its results, that a

friend desires us to ask why, in the name of common-sense, with the many alternative methods which seem open to local use, a stern conservatism should still compel us to the incurrence of so much worry!

The old half-round tile—it is pointed out—is about as crude a material for roofing purposes as can well be imagined. Even presuming that it is of good quality as to the clay used in its preparation, and sufficiently burned—two presumptions which can, unhappily, rarely be made with confidence—its use is attended with risks which may at any moment nullify reliance upon it. The gambolling of our over-friendly crows, the falling of a giant leaf from any of the palms which overshadow our dwellings, and a variety of other possibilities, may at any moment undo the anticipated result to excellence of quality and careful placing in position. To this risk must be added other considerations which appear to render some innovation on established practice desirable. The exceptional weight of these half-round tiles, when laid with the lavishness as to number which can alone insure a tolerably watertight roof over our heads, is regarded as one of the prime factors of the high cost of domestic building among us. As the result of this great weight the framing of the roofs, even of those as low as 12 or 15 feet in span, has to be of a rather expensive kind. Few of the local woods in use as rafters can bear that weight unless by the provision of framed trusses. Palmyra is, perhaps, the only timber that might be trusted to do so, and that scarcely for spans in excess of 15 feet, which is assigning a narrow limit of width for most of our domestic living rooms. As with the roofs so with the walls. These latter are almost invariably sheltered from the sun by verandahs; and were it not for the great and unnecessary weight they have to carry, it is supposed that fourteen or even nine inch walling might be used where it is now customary to build eighteen inch or even two foot walls. Then the slope to be given to the roofs to secure free flow of water is said to be in excess of what would be required for some more scientific method of covering, rendering necessary a greater length of rafter than would otherwise be required. Altogether, if the whole of these several points are taken into consideration, it would appear that some considerable cost is involved by the use of these half-round tiles beyond what would have to be incurred under other conditions. Local house rent may consequently be said to be in excess of what it need be, were the old-fashioned tiles superseded by some more suitable form of covering.

Shingles such as are largely used upcountry are scarcely fitted for general adoption, and thatching of any kind, results in annoyances peculiar to itself, while zinc or iron sheeting must be prohibitory owing to the heat of our tropical sun. Therefore although all of these materials are possessed of the one desirable element of lightness, we can scarcely recommend that any of them should supersede our present system. Slates, it seems, would be too costly, as regards first outlay to be taken into general use; though we should like to see this matter examined a little more closely in the light of the figures we quoted for Monghyr slates the other day. It is not unlikely it would be found that with slates the reduction in weight would enable houses so covered to be built with a saving of other material which would probably fully counterbalance the excess of first outlay. But it is to improvement in dealing with material locally obtainable that our friend conceives we should look to relieve us from the pains and penalties at present incurred.

In European practice there is quite an infinite variety in the form of tiles made, not one of which has been, we believe, adopted in Ceylon, and there is scarcely a single type which has come under notice which does not seem possessed of advantages over the local half-round tile. But all of these, we are told by an expert, demand more care in manufacture than our local tile. Well, why should not that extra care be given? The tiles in common use in Italy, which have a considerable flat surface with a roll for the jointing, form a perfectly efficient roof, look well, and are so hung by pins to the laths—or reepers as they are locally called—that they cannot shift; while they can be used so sparingly that the weight of a covering of them can be scarcely half that of our usual method. On the whole, therefore, we are inclined to recommend that machinery be used for their production, as high quality of manufacture would be thereby attained; and it is believed that the enterprising individual who would import such machinery and set to work to make the Italian tiles on a sufficiently large scale would soon find his outlay well repaid by their large use. Whether this suggestion for a remedy to the present state of things is the best that can be offered we do not pretend to say; but it does seem that there is room for improved methods of covering our houses.

BALLADE OF THE TEA SEASON.

SUNG BY A WEARY CHAASZEE.

The willow blossom, white as snow
Drifts gently on the summer breeze,
Along the Bund swift brokers go
Glad with expectancy of fees;
The weary coolie rests and sees
The sunlight on the river chased,
Soft comes the hum of laden bees—
Ah! I have many teas to taste!
Oh, merry May! 't were sweet, I trow,
To lie beneath the spreading trees
Where daffodils and daisies grow,
To rest and dream in perfect ease.
Alas, for me are none of these,
Around me is the noise and haste
Of brokers' haggle, weighers' squeeze—
Ah! I have many teas to taste!
Here in my tearroom damp and low
I dream of sunny verdant leas,
And sadly wander to and fro
Between long tables strewn with teas;
Soon riverborne towards the seas
The fleetest steamers will have raced,
And things will slacken, by degrees,
But—I have many teas to taste!

Evoy.

Madame! when first the season's teas
Your dainty table shall have graced,
Think of the miserable Chaaszees
Who still have many teas to taste!

Hankow, 6th May.
—N.-C. Herald.

SOMETHING LIKE A WINDSTORM.

The *Indian Planter's Gazette* to hand today has the following report of a storm such as is very rarely indeed paralleled in Ceylon:—

“North Luckimpore, 11th May.—A tremendous storm of wind and rain passed over Harmatti tea garden on the afternoon of the 1st instant extending in width about two miles, levelling and breaking a large number of forest trees. Throughout the garden only two trees weathered the storm, the others were all uprooted doing great damage to the tea, the corrugated iron was blown off half the tea houses and half the leaf withering houses, the iron twisted and in some instances carried away about 100 yards, the walls of the godown blown down and some 13 coolie houses levelled to the ground, while most of the coolie houses were more or less damaged; the rain was blown right through the Bungalow. The

storm did not last more than ten minutes and gave no warning whatever of its coming. Fortunately, no lives were lost. A storm of this kind is bad enough at any time, but particularly so at this season of the year when all was in readiness for the manufacturing season. The manager consoled himself that the forest trees in the garden could not again be uprooted and put on a large force of men to clear away the trees from the tea, and all other available men hands put on to repair the damage to the various buildings. Young shoots, two feet in length were broken right off at the axles by the wind, besides a large number of smaller ones. We have had only one storm approaching this during the last 25 years, it was accompanied with hail; luckily the storm of the 1st instant was not."

TEA.

"China," says Barclay's Complete and Universal Dictionary published just eighty years ago, "is the only country from whence teas are imported." It would be well for foreign residents in China, and for the owners of steamers trading to China, if this were still true. Unfortunately the truth of this statement has, in the last few years, been becoming fine by degrees and beautifully less, and soon the compiler of the encyclopædia of the period, for we cannot now compress complete and universal knowledge into a one-volume dictionary, will have to write that China, the original home of the leaf, is one of the few Asiatic countries from whence no teas are imported into England, India, Ceylon and Java now have circulars to themselves in Mincing Lane, which are enlivened by occasional depreciatory references to this effete empire; even the Malay Peninsula is beginning to grow tea, and the cruelty thereof especially is that it is Chinese who are adding this one to the wounds from which their native country's once leading trade is expiring. China may well say to her unfilial children:—

"That eagle's fate and mine are one,
Who, on the shaft that made him die,
Espied a feather of his own,
Wherewith he went to soar so high."

For it is by not following Chinese methods of preparation that India and Ceylon have become such fatal competitors to China. They cannot even be accused of stealing their seed from China, except in part: it was the discovery of the tea plant growing wild in Assam that first turned the thoughts of Englishmen in India to the possibility of cultivating tea there; a possibility which has grown so rapidly into so lucrative and magnificent an actuality. Not that the China trade is dying without friends at home, who still profess to hope that a recovery is possible. We read in a recent circular of Messrs. J. C. Sillar & Co. that their remarks about Indian teas are having an effect in England, "and sooner or later, the popular taste will undergo a change regarding them." And they add, with a feeling of disgust that the British taste should be so vitiated, that "other nations are not so stupid as poor John Bull, to mistake the muddy, mucilagenous appearance of the liquor of Indian teas for strength." It is pleasant to see such old China hands as the Sillars still trying to defend our trade; but there is too much reason to fear that it is a forlorn hope. The doctors in China have consulted over the case of the moribund, and their proposed cures have been duly collected and published by Sir Robert Hart; but the Inspector-General of Customs himself sees little chance of their prescriptions being followed, in fact the measures he recommends as practicable would hardly do more than skin and film the lucer o'er.

Yet no one who saw the flight of tea-swallows

passing through Shanghai on their way to Hankow this Spring would believe that they were going up to an exhausted field. It is true that they were all full of sinister prognostications. Year by year, as unimpeachable statistics prove, the consumption of China tea is falling off at home, and on the other hand the first crop of Hankow tea is to be a very large one. It has been said—and the same has been said no doubt in other trades—that in the tea trade you should collect all the information from figures or otherwise that you can deduce therefrom the wisest course, and then take the opposite. Is this the maxim that tea buyers are going to follow? The finest tea by first steamer, say the experts at home, should not cost over sixteen pence a pound; and already we hear that six pence a pound more than this has been paid. That, it is explained, is only an isolated purchase; the buyer wants a small parcel to catch the mail. Unfortunately, these isolated purchases set the note to which the teamen tune; and with a hundred buyers, English and Russian, eager to melt their credits, the teamen's scale is apt to prevail. Messrs. J. C. Sillar & Co. are not the only people who see signs—though possibly the wish has too large a share in the paternity of the thought—that the English taste is backing to China teas; and buyers who are conscious that they have paid too much and that the tea is going forward too fast will perhaps solace themselves with this hope. To them we may recall the warning of, among others, Messrs. George White & Co., who estimate the total requirements at home this season at 225,000,000 lb., of which India is to furnish 100,000,000 and Ceylon and Java 45,000,000; so that only 80,000,000 lb. will be wanted from China. "From all accounts," they say, "there will be no lack of tea in China, as they point to a 'bumper crop' in the north, and it remains to be seen whether merchants will ship to this market with some regard to our diminishing requirements from that quarter, or whether we are to be over-supplied, as has hitherto been the case. Over-supply has been the bane of the London market for years past, and has brought about the present low level of value, which there seems little probability of raising until a farther marked falling-off in China shipments is brought about, or fresh markets can be found for the sale of Indian and Ceylon growths." There is the disheartening fact for the China tea-man; there is no question of over-supply from the British possessions; all they produce will be taken; it is only a supplementary supply that is wanted now from China; and with China tea in this secondary position, to what end all the trouble that Sir Robert Hart and his correspondents have taken to investigate the best methods of reviving the quality of the China leaf?

The China tea trade as a whole is thus a striking instance of the irony of fate, and one branch, closely connected with Hankow, gives a special instance of this irony. The appeal in the Conference Case was still going on at home recently, and the principal defendants, who led the efforts of certain ship-owners to keep the Hankow trade to themselves, are the managers of the celebrated Glen line. This year, we are informed, not one of their steamers proceeds to Hankow to load for London.—*N.-C. Herald*, May 11th.

ANGLO-DUTCH TOBACCO COMPANY.

The statutory meeting of the shareholders of the Anglo-Dutch Tobacco Company was held on the 15th inst. at the offices, 2, Token-house-buildings; Mr. David Brown in the chair.

The Chairman, in the course of a statement as to the position and prospects of the company said:—I think it well to take the opportunity of not only bringing before the notice of the shareholders the prospects of the company, but to give you a short outline of how the tobacco trade in Sumatra has developed. Tobacco cultivation was commenced in Sumatra in 1865, and in that year 189 bales were sent to Amsterdam and sold at prices which I should judge from the reports—from the evidence of the statistics—did not pay, as in 1866 and 1867 there was a slight decrease. In 1868 the cultivation assumed larger proportions, and 890 bales were shipped to Amsterdam, and realised an approximate valuation of £17,000. It is needless for me to follow the whole course of the tobacco cultivation—it is enough to state that the wonderful extent of cultivation amounted in 1886 to 139,512 bales, at an approximate valuation of £2,700,000. Naturally you would have supposed that the prices, from the increased production, would have been affected; but the demand has kept up with the supply. Looking over the same statistics, which are almost official ones, and can be vouched for by the leading brokers in Amsterdam, we find that the prices which opened at 2s 4d per lb. reached the highest point in 1873, when they touched 3s per lb. It was evident that the supply was rather in excess of the demand up to 1880, as the price dropped till it reached 1s 10d per lb. From that year, however—I believe, from the supply required by America—the prices gradually and steadily rose, till in 1886 we have the highest valuation, when it rose to 2s. 7d. per lb. A great deal has been said about the 1887 price; in that year the average value was very low, and it was very easily accounted for. It was a bad year for the planters; they had a wet season, and that is fully borne out by statements in the report of Messrs. Bigner and Herschel, tobacco brokers of Amsterdam. They end up their statement with regard to the future thus—"We still retain our good opinion for the future of Sumatra tobacco will be just as well appreciated as now, and that the demand will even grow larger." That this prophecy has been fulfilled there is not the slightest doubt, for the prices of this year are very much better than those of 1886. A few sales only have taken place this year; but I had better quote the first sale. The first was a sale of Deli tobacco, which in 1883, with a percentage of broken leaf of 25 per cent., fetched c. 141. In 1887, with a percentage of broken leaf of 16 per cent., it fetched c. 145, and in 1888 it fetched c. 155, with 50 per cent. of broken leaf in it. This is not an exceptional case at all; it has gone through all the notes we have received of the sale. I should be glad to show you the comparative prices as compared with last year, and I calculate that it varies from 25 per cent. to 75 per cent. A sale took place on May 10th, and there were at the sale several parcels belonging to the Amsterdam Deli Company, which were sold at an average of 157 cents. Of these parcels, immediately after the sale we received advices that a lot valued at 160 cents was resold at 205, a further lot, valued at 128½, was resold at 175 cents, and a further lot, valued at 119 cents, fetched the enormous value of 185 cents. The agents, in writing me, say that the competition was most exciting, and there were more bids made than he had ever seen before. There was some competition between the American and German buyers, the quality being good, and there being a great demand, owing to the shortness of the quantity last year. It is necessary for us to make a distinction in the prices. There are in Sumatra three well-known tobacco growing districts—Deli, Lankat, and Sirdang. In Deli the tobacco produced sells at an approximate average of 2s. 7½d. per lb.; in Lankat, 2s. 9d.; while for Sirdang 2s. 2d. was realised, showing that while Lankat is superior to Deli, Sirdang is rather inferior to both. Our property is in Sirdang. To buy property in either of the other districts is almost impossible, except at excessive rates. I can vouch for the sale of a portion of land which I sold in Deli for £40,000, and, except at very high rates, it is almost impossible to purchase it. It is impossible to obtain virgin land in Deli such as we have in Sirdang: I shall now

go on to the cost price of tobacco, so that we may arrive at some conclusion as to the probable margin of profit. The cost of production is from 1s. 4d. to 1s. 6d. per lb.; but, of course, we must have good management to do that. With good management it should not exceed 1s. 6d., including sale charges at Amsterdam. That leaves a good profit on the average sale of Sirdang tobacco, which in 1886 fetched 2s. 2d. per lb. The estates that the company now have been pronounced by the manager to be the best in Sirdang, so that I think we are justified in taking this 2s. 2d. per lb. as a fair average quotation for what we should get for our product, without taking note of the rise in the recent sales. In addition to this, we have the great advantage of having a large amount of virgin soil, and also estates in thoroughgoing order, fully stocked with everything that is required for a tobacco company, and they have produced this year 500,000 lb. of tobacco. We have, moreover, a guarantee for the present year of £6,000 profit on the present crop. This has not been founded on any doubtful figures, but was based on absolute calculation of what one of the vendors' estates made in 1886. With these facilities, and the subscription of capital (upon which all calls have been paid), and with good management, we think our company will bear comparison with any company which has been started in London for the cultivation of tobacco. I do not wish to disparage any other company; I wish simply to put before you the facts, and allow you to draw the comparison, knowing the actual position of the company—that we are in as good a position, if not better, than any other. Nearly everything in the profit of the company depends on the management, and I think the shareholders will have some satisfaction in knowing that most of the members of the board have an intimate knowledge of the business, and have devoted themselves to the cultivation of tobacco in Sumatra, and have an actual practical knowledge of the working. Two of them have lived in Sumatra for many years, and are judges of the soil, acquainted with the native rajahs, and have been on good terms with the governing authorities. I think, therefore, you have a good property. We cannot, of course say anything about the future of prices; but if prices hold, as they promise to do, the prospects of the company promise to be very successful. I read in the paper this morning a report that the Dutch had been coming into contact with the Achinese at Edi, and the public may think that will affect the tobacco industry in the southern districts of Sumatra; but the railway facilities are so great that any fear is out of the question. The Achinese are not natives of the country, and the only possible harm they could do would be out of mere revenge, which the Dutch company could cope with and prevent. If there is any question any shareholder would like to ask I shall be very glad to give any information.

Mr. Henderson asked how long the soil would continue to bear tobacco? How many crops would the same soil give?

The Chairman said the average cultivation on estates of similar size to theirs was 500 acres. They possessed about 27,000 acres, of which they might fairly say that 16,000 acres were good for the cultivation of tobacco. Taking 500 acres—or, if they extended the cultivation, they could go on for sixteen years without using the same ground. In Deli and Lankat it had been found in all cases that the second crop was quite as good if the ground was allowed sufficient time to rest—from five to ten years—it was quite as good; if not better. He knew estates in which he was interested where the secret of cultivation had been kept, where the second crop sold at the highest price the estate had ever realised. They knew it would do for two years, but whether it would do for three years they could not say, but that would take them on to fifty years. Perhaps it might be as well to mention that at a sale on May 10th the prices were kept secret; but had recently been divulged, and they learned that the product of an estate next to theirs in Sirdang had fetched a price which was almost unknown, viz., 165 cents, which was equivalent to 2s. 9d. a pound,

A vote of thanks having been accorded to the chairman the proceedings ended.—*L. and C. Express*, May 17.

CATSEYES.

TO THE EDITOR OF THE "STANDARD."

SIR,—Your interesting article of today on the large Catseye recently found in Ceylon is misleading in one particular.

If a true Catseye, or "Cynophane," which we take it to be, it is far more than a "piece of glorified rock crystal." There is as much difference between the gem Catseye and its rock crystal would-be rival as between gold and brass; nay, more—the first is a valuable stone, the second next to valueless.

An analysis by Professor Church, M.A., Oxon, gives roughly, for the gem Catseye—

Alumina	...	76	} Parts in 100
Glumia	...	18	
Ferrous oxide	...	4	
Rock crystal is very different—			
Silicon	...	46.7	} Parts in 100
Oxygen	...	53.3	

We are, sir, your obedient servants,
P. G. DODD and SON.
146, Leadenhall-street, E.C., May 10th.

SIR,—The firm who have written to inform you that the Catseye is not a quartz, that it is the same as "cynophane," and—somewhat superfluously—that it is "a valuable stone" are entirely wrong, except in the last particular. Every one knows that it is a "valuable stone;" the object, indeed of your Article was to assess its properties. But, as any Mineralogist, or any book on Mineralogy—Nicol's "Manual" (page 111), for example—could have informed them, the Catseye, like the amethyst, the opal and a host of other gems, all belong to the quartz family, their distinctive merits being to the presence of minute quantities of foreign matter.

The cymophane (not "cynophane") of Hauy, the prismatic corundum of Mohs and Jameson, is better known as the chrysoberyl, a very different mineral. It belongs to the same family as the topaz. The analysis given by your correspondents is also, as they put it, incorrect. The mineral contains from 68.67 to close on 79 per cent of alumina, and from 18.83 per cent of glucina—not "glumia"—besides a little silica and titanio acid in some specimens, and a trace of other substances. The analysis of rock crystal is also imperfectly given. I may add that chrysoberyl is so unlike the Catseye that it is impossible for any one who has ever seen the two to confound them.—I am, sir, your obedient servant,
F. G. S.

May 11th.

NOTES ON PRODUCE AND FINANCE.
TEA IN FRANCE.

The Paris Exhibition is now open, and although it is not yet in anything like full swing, the control of the Indian tea-room in the Indian Palace is in good hands, and ready for customers. The Indian Tea Districts Association, by arrangement with the Tower Tea Company, have secured the services of Mr. Thomas Lough of that company, and this gentleman means business. He keeps a poet and an artist on his staff apparently, for some neat verses in French are turned out, in which the qualities of tea are extolled, and the most fascinating illustrations are given of the bliss here below which awaits the tea drinker. Mr. Lough believe that the French will take kindly to tea. His company is distributing over France, to the tune of a million copies, a pretty little brochure in French, with dainty illustrations, and they are also issuing a big book to the trade. Although the French doctors talk the usual nonsense about the bad effects of tea-drinking the progress is great. The average quantity of tea taken in each of the ten years previous to and including 1838, was 116,000 kilogrammes; 1848, 146; 1858, 199; 1868, 304; 1878, 318; 1888, 487,000 kilogrammes, a kilogramme being two pounds. Although these figures are small, they justify the opinion that one hears everywhere in France that the demand for tea is increasing. When the native waiters arrive, Mr. Lough ought to carry all before him.

The Kangra Valley planters are annoyed because they think their tea is not properly represented at

Paris. They object to be "lumped" with others. They wish to have a special "Kangra Valley blend" on sale, but this the executive are averse to. The Kangra Valley planters think their teas are just suited to a Continental market, and to blend theirs with tea from other districts would be a mistake. The executive of the Indian Tea Association, at Calcutta, on the other hand, do not seem to approve of the proposal put forward by the Kangra Valley people.—*H. & C. Mail*, May 10th.

WESTLAND'S TEA ROLL BREAKER.

In the course of a letter before us, Mr. James Westland of Matale East says of this roller:—

"The small tea roll breaker here, with a coolly driving and another feeding, certainly does its work quickly and well and without taking the twist out of the leaf.

"Here are sales of the Forest Hill estate tea, which, in process of manufacture, passed through it:—

April 27th,	B. P. 85c.;	P. S. 40c.
May 2nd,	B. P. 86c.;	P. S. 45c.
May 16th,	B. P. 76c.;	P. S. 38c.
May 29th,	B. P. 77c.;	P. S. 39c.

"When asked at the Exhibition, what the tea had been sold at which passed through the new machine, I quite forgot to mention Forest Hill tea sales in the local market; as to the capacity for work, it has broken up over 61,000 lb. of leaf during this month, most of which passed through it a second time, *i. e.* after the 2nd rolling. In a few days I hope the makers will have the sieve arrangement completed and satisfactorily prove the merits of the machine."

TEA FOR THE UNITED STATES—
FREE OF DUTY?

There seems to be some doubt as to whether any duty is charged on tea imported to America, whether in American or foreign ships. The Consul-General in Calcutta informs us that, according to the latest Tariff Act of the United States, that of March 1883, tea is placed on the free list without any qualification or reference to the nationality of the vessel in which it is imported. But Mr. Morey, the United States Consul at Colombo, appears to be of a different opinion, or why did he advise the Ceylon tea planters to charter an American steamer, so that their tea might be imported free of duty, when this would also be the case if it was sent in any other vessel?—*Calcutta Englishman*.

THE SEYCHELLES ISLANDS.

We announced on Tuesday that the Queen had been pleased to reform the constitution of the Seychelles Islands, and to appoint an administrator subordinate to the Government of Mauritius, with an Executive and Legislative Council for the Administration of that dependency. It may interest our readers if we call to mind the most remarkable characteristics of this little group of islands, situated in the middle of the Indian Ocean a thousand miles east of the African Coast and from Mauritius. There are altogether twenty-nine islands, of which *Mahé*, bearing the same name as the small French settlement on the Malabar Coast, is the largest, containing an area of about 70 square miles. The other principal islands of the group are called Pars'in, La Digue, Ourieuse, Félicité, Isle Aride, and St. Aune. The larger islands are granitic, resting on an extensive bank of sand and coral. To the S. W. of the Seychelles is a small group of islands called the form *Admirantes*, which

an appendage to the larger group of the Seychelles. The Seychelles are mountainous, rising in some places abruptly from the sea. The vegetation is luxuriant and tropical, for the islands are close to the equator. The population consists of 15,752 souls, of which 7,976 are males, and 7,776 females, thus reversing the order in other parts of the world, where the number of females invariably predominates. The revenue in 1887, amounted to R1,71,162, and the expenditure to R1,28,118. The value of the exports exceeded that of the imports by nearly two lakhs of rupees. During 1887, sixty-seven ships touched at these islands, including twelve men-of-war. Education is not neglected, for there are twenty-two Government schools with 1,801 pupils. The inhabitants are of several races and creeds, French, English, African, Madagascan pure bred and half-bred.

The principal port of the Archipelago is Victoria, on the north-eastern side of the island of Mahé. The Seychelles enjoy peculiar immunity from the dreadful hurricanes which sweep across the neighbouring seas. The islands produce a large amount of timber, useful for ship-building purposes. Coconut trees grow remarkably well, and so does cotton, both of which furnish the greater part of the articles of commerce with the outer world. Coconut oil and tortoise shell are also exported in considerable quantities. Rich people in the island, *i.e.*, people rich compared to the majority of the inhabitants, show their prosperity by keeping preserves of tortoises, as aristocrats keep deer in England. Some of these tortoises have Vandyck edges to their shells, and are valuable for making tortoise-shells combs. A single shell will sometimes fetch as much as £10. The want of labour is felt everywhere. The introduction of coolie labour from India has been long under consideration, and it is strange that more has not been done in this matter, considering the natural fertility of the islands, and their important geographical position. The truth of the matter has, however, been recently pointed out by a visitor, who states that "the people have not sufficient energy to work with their own hands and no money to pay for labour, and they are consequently being slowly ruined. Everyone is on the edge of starvation in the midst of riches." Most of the houses are built of wood thatched with the leaves of the coco-de-mer tree, and are of the poorest description. The scenery is said to be magnificent. "The little islands have groves of waving casuarinas on their tops, and fine large-leaved trees shading the sandy shore all along, varied with patches of coco-nut and bread fruit, and above the deep purple-red, stony-topped hills, with forests between the famous coco-de-mer trees are dotted here and there among them like golden stars." The fruit of this peculiar tree is a kind of twin fruit like two coconuts joined together. Great virtues as medicine and antidote were supposed to reside in these fruits. The old belief was that the fruit was produced on a palm, growing below the sea, (hence its name) whose fronds, according to Malay seamen, were sometimes seen in the quiet seas on the Sumatra Coast. The medical virtues of the nut were famous amongst all Eastern people, including the Chinese. The East India Company once paid as much as R300 for one of these nuts, in order to make a present of it to a Nawab.

Very severe quarantine regulations were some years ago imposed on the Seychelles islands by the Mauritius Government, and all trade was consequently stopped. Such distress ensued that Mahé began to feel the want of the simplest necessities of life, and every thing went up to famine

prices. The poor could not afford to buy rice, and were too weak to do any work in their own fields. Those who own coconut plantation in the islands, are usually well enough off, but the people who have to subsist on agriculture are indigent for the reasons specified above. Want of water, too, is almost universally felt. The people on the *Ile Aride* have to use the brackish water that filters through the sand from the sea, and *La Digue*, a large fertile island, with nearly a thousand inhabitants, is almost as badly off for this prime necessity of life. *Curieuse* island is set apart for lepers, as is Molokai in the Sandwich Islands in the South Pacific. The first thought of the poor creatures sent there is to procure a coffin, for otherwise they are buried without one: "They go on scraping up money to buy one, or working day and night till they have made one, when they put it into their huts, and sit down content." Altogether the conditions of existence of the inhabitants of these Isles do not seem very happy notwithstanding their fertile soil, and the beautiful scenery which surrounds them. Let us hope that the autonomy just granted to them may prove to be the starting point of greater prosperity in the future. It seems absurd that Mauritius, situated nearly a thousand miles from this dependent group of islands, has long been allowed to exercise an authority over them that has at times had disastrous effects. It could hardly be expected that the Seychelles could prosper under such an arrangement.—*Madras Mail*.

SILK.—The *Kuang-pao* says that in the Kuang-tung province the crop of silk bids fair to be excellent this year; but mulberry leaves are dear so that the poor people cannot afford to rear a very large number of silk-worms. The quality of the silk will, it is anticipated, be good.—*N.-C. Herald*, May 11th.

A PRIVATE ELECTRIC RAILWAY.—Ceylon is rather better off than Scotland in point of waterfalls and the day ought not to be far off when the power at present running waste should be used for electric purposes in different ways. The following is from the London *Times* of May 14th:—

Scotland has so many waterfalls that it is not surprising to find a beginning made in utilizing their power for electric railways. The residence of Mr. J. Monteith, Carstairs-house, has recently been united to Carstairs Junction by an electric line $1\frac{1}{2}$ mile long, running through the grounds of the mansion. Messrs. Anderson and Munro, of Glasgow, are the engineers of the line, which is worked by the Cleghorn Falls, some three miles distant on the River Mouse. A turbine transforms the power of the falls into electricity by means of a dynamo of the Goolden type, giving 400 volts and about 40 amperes. The current is carried by four bare copper wires run on poles and supported by liquid insulators. The metallic circuit is complete throughout, no earth connexion being used. The conductors laid along the line consist of rectangular rods of very pure iron, placed, one on each side, about a foot from the rails. They are supported on special insulators on an elastic fastening of steel, which allows of no side oscillation, and permits the rods to expand freely. These insulators are in turn supported upon iron rods, ten inches high, planted on the sleepers. The gauge of the line is 30 inches, and a handsome carriage, capable of running at a speed of 35 miles an hour, has been provided. The line can be run direct from the dynamo, or through the agency of accumulators, of which there is a supply at Carstairs-house for the electric lighting installation. The line is built for private purposes and chiefly for transit between the mansion and the railway station; but it can be used for farm and estate purposes and has been arranged with branches and sidings to that end.

TEA CULTURE AND PREPARATION:

A FEW PRACTICAL INQUIRIES BY A PRACTICAL MAN.

1. Is not Mr. Armstrong responsible for the statement that the quality of the tea is best when the bushes flush most freely?

2. Have you any information to indicate that the application of manure improves the flavour or strength of the tea?

3. A good deal is now being said about fine plucking and high prices, but surely the men whose success we should emulate are those who combine quantity with quality?

XXXVI.

Matale East.

1. With regard to the first inquiry, I am of opinion that the best tea is not made when the bushes flush most freely. I am rather inclined to think that with the exception of first flushes after pruning, our worst tea is made then. So far as my observation goes, our best tea is made in this district from May to Sept., after the big rush of leaf is over in April.

2. The effect of manure as regards quantity is scarcely questioned: my experience here points to an increase of 200 lb made tea within the year, from a manure costing R54 per acre. This will pay only so long as tea nets 44c per lb, assuming that 17c will cover cost of plucking, manufacture, packing, cases, &c., transport and f. o. b. charges. My own impression was, from tasting the teas immediately after manufacture, that there was a decided improvement in quality equal in value to a 1d to 1½ per lb, but my account sales do not support this, and only show an advantage of ¾d per lb. This however is equal to R6 per acre on the increased yield.

3. Fine plucking *versus* medium or coarse is a very vexed one. Those estates producing fine-flavoured teas with strength combined, such as Hoola, will no doubt with fine plucking pay well, but in many cases a steady fine flavoured tea is not obtainable, even with fine plucking, in which case a medium style seems by far the safer course to pursue.

(OLD COFFEE LAND.)

XXXVII.

Gampola, 11th May.

1. In February and March, when the trees are generally feeling the effects of prolonged drought, the quality of our leaf and of the teas made is most "undesirable"; in April after a good deal of rain has fallen we get a heavy rush of leaf, which gives a tea with a little flavour, but "wanting in the cup," as the brokers say, and there is very little improvement in the quality till July, when the bushes seem to settle down to steady, even flushing. From that time up to about the end of January we get teas with better strength and flavour. All the above presupposes the bushes to be in good heart; I have noticed a great falling-off in quality of tea from bushes plucked for about two years without a pruning.

2. Manure, cattle or artificial, decidedly improves the flushing qualities of tea in poor land, and I should say it improves the strength, but I think it is very doubtful if it improves the flavour.

3. I think a *careful* medium plucking pays best: fine plucking in my opinion halves the yield here, and more than doubles the cost of plucking, besides increasing greatly the cost per lb. of tea, of every other item of cultivation, without giving a corresponding increase in value to make up for the lower yield. Fine plucking makes the bush slat up sooner than medium plucking, and necessitates more frequent pruning. Is it not the case that there has been a greater drop in the value of broken pekoe and pekoe than in pekoe souchong?

G. D. J.

XXXVIII.

Central Province, 11th May.

I have been making tea for the last 10 years, and have been at the top of the list and have also been at the bottom of the list, and my opinion is this:—

1. I am not aware that Mr. Armstrong said this; but I am aware that Mr. Armstrong has done a great deal to place Ceylon tea in the position it now holds; my own opinion is that the best tea is made when the bushes are *not* flushing freely. When the bushes are flushing too freely the result is *more like what you get from tipplings after pruning.*

2. I have no information gained from practical results, but I would think manuring would both improve quantity and quality, but at present prices I would say take what you can get *without* manuring.

3. There is a great deal more that could be said about fine plucking and high prices, and this is a point which a good many planters differ on. There is much to be said on both sides, but as far as I can judge it would pay us all best to go in for *medium* plucking and keep up the quality without sending in too coarse stuff by doing this. We may aim at both quantity and quality, but I defy any man who goes in for quality to get quantity too. Another man who prefers quantity cannot possibly get quality, so I think the best thing for us all to do is to go in for *medium*. Avoid coarse: we are all in the same boat.

PRACTICAL PLANTER.

XXXIX.

Portwood, 11th May 1889.

1. I believe dull weather—when the trees are not over flushing—gives the best and most flavoury teas.

2. I am not in a position to answer this, having no manured tea; but digging certainly improves the bushes and quality of made tea.

3. I believe firmly in plucking regularly, and not fine. I think plucking to produce about 55 to 60 per cent of pekoe the best.

E. GORDON G.

XL.

Ambagamuwa.

1. When bushes flush freely the leaf is tender, with a minimum percentage of baugy shoots, and can be more easily withered, and therefore makes better tea than leaf from a stunted growth due to bad condition of bushes, bad weather or poor soil. During four months following a heavy pruning the bushes flush too freely and the leaf gives a poor liquor. I consider bushes to be flushing freely when they do not show baugy before the third leaf.

2. Application of manure to poor soil corrects the stunted growth of the bushes, making them flush more freely and give better leaf. Manure undoubtedly improves the quality of the tea produced from land where the tea at seven years old does not give more than 250 lb. of tea per acre with medium plucking. When manure is applied to tea on good soil the leaf gives a poorer liquor only for a short period, whilst the manure is most active and producing leaf similar to that after a heavy pruning. Carter's experiments with manure in Chittagong showed that manure improved the quality of the tea (*T. A. Nov. 1885*).

3. Very fine plucking as carried out on some estates consists in taking only the bud and the partially developed leaf attached. This gives broken orange and orange pekoe only. Fine plucking, as done on perhaps a third of Ceylon estates, is the same as very fine plucking with the addition of half the next leaf, that is, half the pekoe leaf. Medium plucking may be said to consist in taking either the same as in fine plucking mixed with a similar proportion of bud, two leaves and a half, or just the bud and two leaves. Medium coarse plucking is, either taking the bud and three leaves attached mixed with some bud and only two leaves attached; or a mixture of bud, two leaves and a half, and bud, three leaves and a half. This gives about 50 per cent of true pekoe souchong, broken tea and dust. Very fine plucking gives fancy teas and fancy prices which however can only be secured for a limited quantity. There should be more discrimination between fancy or fine teas and fine quality teas. What in most cases will pay best is fine quality appearing in a large percentage of true pekoe souchong (not pekoe leaf classed as pekoe souchong as is so frequently done for *éclat*) carefully manufactured

from leaf plucked medium coarse. This class of tea, good enough as a self tea for retail at 1s 9d per lb., is what we should ship to oust China teas. M.

XLI.

Bogawantalawa, May 14th, 1889.

1. I think the best tea is made from bushes that have run 6 to 12 months from pruning; after the twelfth month the teas—in dry weather—get poorer, but with showery weather the good character remains, until the 18th month on good jāt, and 15th month on poorer jāt. After these periods the teas are decidedly inferior in flavour, although possessing fair strength.

2. Bulky manure improved the appearance and flush of the small piece to which it was applied; I noticed no difference in character of teas from the manure.

3. Medium plucking, *i.e.* tip with 2 leaves attached and half the next leaf, if suitable, gives the best results; but if the half leaf is hard it should certainly be thrown away. On banji shoots the top leaf only, and half the next leaf if not hard. Careful plucking, with an absence of hard leaf, gives better results than fine plucking. W. P. M.

XLII.

Matale, 5th May 1889.

I am not an authority on tea, and therefore my opinion is not of much value:

1. I doubt if Mr. Armstrong ever made such a statement, "that the quality of the tea is best when the bushes flush most freely," and I can hardly imagine that the bushes can give a better quality of leaf during their heaviest flushes.

2. I know of none, beyond the opinion that a tree kept in a healthy condition is better able to produce a healthy foliage than a tree is likely to produce, growing in exhausted or worn-out soil. Take the bushes round an old cattle-shed: even the same jāt of tea looks better than it does on the unmanured or worn-out portions of the estate.

3. Medium plucking is, in my opinion, what will pay best in the end. Fine plucking, before the flush is ready to pluck, will, it is said, "run bushes without a doubt;" and to quote from the same writer, "the teas are not so full of good flavour, though they have the flavour of fineness, the proportions are finer, but the quantity is greatly lessened;" and I believe he is right too when he goes into say "the greater average value of the tea per lb. does not make up for the loss in quantity, neither for the injury done to the plant especially if carried on from year to year." What is medium plucking? Opinions vary so on this point, that, young tea planter that I am, I give my opinion, that two leaves and the bud, *only*, leaving one fully developed leaf on the young shoot, may be considered medium plucking. OLD COFFEE HAND.

XLIII.

16th May 1889.

1. I agree with this view.

2. I am of opinion that the quality deteriorates in proportion to the extra quantity obtained by manuring (artificial).

3. With the present low range of prices, fine, *i.e.* expensive, plucking does not give such good returns as medium plucking. G. A. T.

XLIV.

Sembawatte Estate, Nawalapitiya, 17th May 1889.

1. Mr. C. S. Armstrong may be responsible for this statement or not. If he is, he is perfectly correct: as a rule, bushes flush more freely before and for some days after full moon, during which period a better quality of tea is manufactured.

2. Application of manure does not, in my opinion, improve flavor; it may add a little to strength, and of course gives an increased yield.

3. No fine plucking in these days, or rather plucking on the Cameron system (2½ leaves and round in 8 days) will procure us the prices ruling from '82 to '86. Quantity and quality combined equal a medium, and this I consider the best mode to tide over this depression. D. F.

XLV.

Mahatenne, Elkaduwa.

1. I do not know what Mr. Armstrong may have said on the subject of the best tea from the heaviest flushes.

2. I believe that a suitable manure can improve the yield per acre and the strength of the tea in the cup, but flavour is a matter of soil and elevation. I do not think that artificial manures alone of a stimulating character give any permanent strength to the plant, although the yield may be increased for the time being. A stimulating chemical manure without bulk of some sort to back it up, when the soil is poor, is not advisable, except perhaps in very small quantities as a tonic to the plant.

3. A medium style of manufacture, as regards leaf, is, I believe, the most suitable in the end for both the producer and the market. W. H. A.

XLVI.

Central Province.

1. I think the best tea is made in fine weather when there is not a big flush on. In showery or wet weather, when the bushes flush freely, the leaf is wet both outside and in, and poorer tea is the result. I consider the best tea is made three or four months previous to pruning, and that is not a time when the flush comes too freely.

2. I cannot speak from personal experience as to improved quality of manured tea, but if Indian teas are improved by the application of manure, why not our teas? Colonel Money, who is, or at any rate who was, acknowledged as an authority in these matters, says that manuring doubled his yield, and improved the quality. Mr. F. Carter of Chandpore tea estate in Chittagong goes further and gives figures, which I have no doubt are trustworthy. Writing of the application of bones and castor cake he says, that when the ground is adequately manured the value of the tea is enhanced 2 pies per lb."

3. Medium plucking by all means. I have never been in the position of being able to pluck fine; it is no doubt a delightful sensation, but few there be that find and experience it, but even as good policy I doubt very much if it would pay. Pluck regularly, pluck carefully and wither with plenty of light and air, and a good tea will be the result. T.

XLVII.

Dolosbage.

1. I am not aware that Mr. Armstrong made the statement, that the quantity of the tea is best when the bushes flush freely. My experience is that the best tea is made from a *strong* flush (if taken in tune) when the leaf is full of sap, but not till about six months after pruning. I think September, October and November the best months, and January and February the worst, for making good tea.

2. I cannot say whether tea if manured would give extra strength and flavour, but I expect it would improve in strength.

3. In answer to this question I agree with every word your correspondent from Dikoya "W. F. L." has written. The price of pekoe souchoing has only gone down 1½d per lb. while broken pekoe has gone down 6d during the same period. J. A.

XLVIII.

Upper Maskeliya.

1. I think so; and I agree, if the first few flushes after pruning are not taken into account.

2. I have done no manuring, but on an adjoining estate tea has been manured, and the property in question is head and shoulders above the majority of Ceylon estates in the price the tea fetches. I am unable to say what proportion of the estate has been manured.

3. Certainly when the man is found; as yet I have not heard of the combination having been realized. The nearest approach I have any knowledge of is 200 lb. an acre, and about 1s 4d per lb., which should show a fair margin of profit, but still this cannot be called *quantity* and quality; it is none the less, however, a state into which many of us would be pleased to be called. M.

XLIX.

Madulkele, 18th May 1889.

1. I do not know if Mr. Armstrong or any other has committed himself to this statement that the best teas are made when the bushes flush best. My experience would lead me to believe the reverse, *i.e.* that when growth is slowest and the flush checked by cold or wet weather the best teas are then manufactured. A correspondent from Matale has, however, said very truly that the reason of a belief in poorer teas being made from the heaviest flushes has to be looked for in the superintendent being unable to get round in his usual 7 to 8 days in heavy flushing weather, and the flushes running away and getting hard in consequence.

2. I have done a lot of manuring during the last two years, and find there is no difference in strength or flavour between teas from manured or unmanured fields. Increased quantity you will always get by cultivation. The manures I have experience in, I would place in the following order of merit:—

1st. Cattle-manure and crushed white castor cake mixed and forked in.

2nd. Cattle manure alone well dusted with powdered phosphate of lime to fix the ammonia and make the compost distasteful to the omnivorous white-ant.

3rd. Double kainit (sulphate of potash) by itself forked in.

4th. Castor cake by itself.

5th. Simple forking.

I will never apply castor cake by itself again. Although you get the flush for the time being, the evil after-effects on the trees are most apparent. Castor cake with cattle-manure is very different and stands first in my order of merit. Double kainit is excellent, gives heavy flushes, trees make lovely wood and no evil effects visible. Simply forking after first treatment seems to have no effect at all.

3. Who gets quantity with quality? I fancy I have hitherto plucked coarser than anyone in the Island, going in properly for quantity without quality. It paid me very well to do so till January 1889, when the market for coarse teas went all to the bad, and I have now had to change my system and go in for medium fine plucking. With medium plucking I expect to get a yield of over 800 lb. per acre off my 800 acres, and can place it in London all charges included for 7½d per lb. I do not think finer plucking would show any difference in profit to above method. The teas would cost more for a certainty, and that they would fetch more is an uncertainty. I think I'll stick to my present method and pluck medium fine, being content with an average a little above cost price for the present. The approaching crisis must sweep many away, but I don't think Ceylon will suffer as much as others.

T. D.

L.

Maturata, May 20th.

1. I think that the quality of the tea is poorest just after pruning, and *vice versa*, at its best when the bushes have got their matured wood on them, provided you have fine weather. Too much rain gives a long joint, and a weak-in-liquor leaf.

2. Have had no experience on this point.

3. I believe in medium plucking, say 300 to 350 lb. per acre, hard rolling, little fermentation.—DROMIO.

LII.

Awisawella, 18th May.

1. I refer solely to the lowcountry. Our trees flush most freely when the April rains set in, after the drought of February and March, and at this time the teas are weak and flavourless. I think this is chiefly due to the poorness of the sap, though the difficulty of obtaining a good wither and fermentation may in a measure account for it.

2. I have no practical experience of the application of manure, but I have found that young vigorous bushes in good soil give tea of better flavor and strength than similar plants in poorer soil, and that the tea

loses its original strength and flavour as the soil becomes exhausted. It seems reasonable to conclude that suitable manures would keep up or restore these.

3. Growth is so rapid and vigorous and our leaves so far apart that we cannot pluck "fine" in the ordinary sense. We may by getting round quickly pluck close and hard; but I do not think it would permanently improve the quality of our teas, though it might give a larger proportion of finer grades. Attention to the health of our trees and medium plucking give the best average quality,—we can never compete with upcountry teas for flavour and fineness. These depend on soil and climate. The lowcountry must trust in a great measure to quantity combined with cheap production and transport.

B.

LIII.

In the South, May 20th.

1. I am not able to say whether Mr. Armstrong is responsible for the statement "That the quality of tea is best when the bushes flush most freely." My own experience is that a great flush sent up by rains after drought and heat does not turn out such good tea as when the bushes are flushing moderately. This is especially the case in the lowcountry. From 2,000 ft. to 3,000 ft. elevation I never found the difference so marked.

2. I can only give the results of the manuring of one small field. The soil was so poor most of what should have been the flush only got the length of poor feeble banjy. The manure had the effect of making it flush fairly and to give good tippy tea which could not be got before manuring. The liquor was stronger doubtless; as to the flavour and whether the manuring will pay, "judgment reserved for the present."

3. This is a very important matter, but how quantity and quality are to be reconciled so as to go together "beats me." What might be called a fine medium plucking is, I believe, the most profitable; coarse plucking (though not always kept in view) reduces your fine qualities. The prices of all qualities are amalgamated in the roller; consequently the more coarse leaf you roll with the fine, the more you detract from the strength and flavour of your broken pekoes and pekoes. Though foreign to the inquiry, I would here add that nothing reduces the quality and flavour of tea equal to blossoming and seed-bearing. On some estates where there is much low jät tea, good and carefully made teas are often largely sacrificed by mixing with tea plucked off the bad jät after they are into a mess of blossom buds.

W. M.

LIII.

Cloudlands, 18th May.

I am unable to give you any information regarding queries No. 1 and 2, and shall confine myself to answering the third and most important question.

Undoubtedly to make tea pay you must combine "QUANTITY WITH QUALITY." I thought all this was satisfactorily settled long ago, and that only a very few plucked fine. That is to say an average of 85 lb made tea per acre. It is absurd to imagine that in a financial sense this pays, and it never is attempted except by two distinct class of planters:—First, by the enthusiast, who wishes to see THE MARK,—and his name also—figuring in brokers reports and newspaper paragraphs; or, again, by the proprietor who is anxious to dispose of his estate, and with that object in view gives his superintendent carte blanche to pluck as he pleases, and not take quantity into consideration so long as he can "top the market," and get up the name of his property in the vain hope of speedily "selling out." The former is soon found out and becomes a target for ridicule; whilst the latter never deceives anyone except himself. I have been from the very beginning a disciple and follower of Mr. James Taylor of Loolocondra, who, to my mind, has fully and clearly demonstrated the practicableness of obtaining "quantity with quality." I know for a fact that Mr. Taylor has obtained as high as 360 lb average per annum from his old tea, and it's quite unnecessary here to enter into his prices, as they are well-known to those who study the "Market Reports." I

am aware of his inherent modesty and great disinclination to appear in print, at the same time cannot help feeling that if you appeal to him on behalf of his brother-planters at this serious crisis he will readily respond, and give all the varied experiences on the subject from his stores of knowledge.* Mr. Taylor told me long ago that the secret of making good tea consisted in paying attention to the pluckers. According as you pluck will be your output. And your Bogawantalawa correspondent clearly illustrated this important point in a very happy manner lately. He told us that nine out of ten planters thoroughly understood the proper system of plucking THEORETICALLY; but alas! how few ever saw it efficiently carried out IN THE FIELD. That is the key-note of success in tea manufacture, viz. CAREFUL PLUCKING, in fact tea is made or marred in the field; and this trite maxim cannot be too strongly impressed upon all concerned, and ought to be printed in large letters over every factory door throughout the country. My own ideas of combining "quantity with quality" is, if you secure from 150 to 250 lb. made tea per acre from old coffee lands according to varied circumstances, and from 300 to 400 lb. per acre from tea planted on virgin soil,—the average price for same, at present ruling rates, to come to 1s per lb. in London, or, say 60 cents per lb. laid down in Colombo. From my experience they are reasonable and easily obtainable figures, PROVIDED great care and attention are exercised throughout, viz. in pruning, plucking, and manufacture.

OLD CLOUDLANDS.

LIV.

1. With smiling weather, but moist enough, and at six months to one year after pruning, I have found the quality of the made tea best. At first after pruning, the leaf is too full of watery sap, to give good liquor, and it is rank and deficient in flavour. These faults may be much mitigated by extra withering, which will permit longer and harder rolling or manipulation, without waste of the cell contents, in which are all the elements of the tea. After one year, I think there is a falling-off to thinness with *medium* plucking, excepting the last few rounds, when usually all buds are harvested before pruning. Pruning may be done at intervals of 20 months or so, as two years is somewhat too long for this elevation.

2. Manure: bulky stuff, cattle manure, vegetable compost, with wood ashes, &c., seems to almost double the yield; but in the few cases falling within my ken, neither the liquor nor flavour of the tea had been perceptibly improved. I got the strongest and best flavoured tea from a poor jāt grown unmanured on a sharp ferruginous soil, of course with a moderate yield. With present prices manuring must be in abeyance, unless under favourable conditions, meaning production on the spot, or very cheap transport. The manures noted may be profitably applied by forking in, or in shallow pits, during lulls in plucking or other spare time. The aeration of the soil by either mode is beneficial.

3. *Medium* is likely all round to prove the best, with either high or low prices. *Coarse* plucking requires no comment. Good tea cannot be made from it. *Fine* plucking is to be avoided, I think, for the reason that a fairly workable quantity of tea is not yielded by the trees in the intervals of pruning. Now pruning is a very expensive work, including nearly 6 months' loss of yield after each operation. As soon as the tree is in order after pruning, with *fine* plucking begins a process of punishment, which long before the proper time diminishes the yield of leaf to an unprofitable level, leaving the trees not unlike good serviceable *besoms*, stunted and dwarfed in growth and not unlikely hurt in vigour for the succeeding season! With *medium* plucking the *tips* will be as good and nearly as numerous as with the *fine*. The *pekoe* and *pekoe souchong* leaf should be rather more flavoured the cell contents being more matured, and a moderate percentage of *souchong* does no harm, but shows that the trees are not being overplucked,

* How does "Cloudlands" know that he has not taken a part?—Ed.

It should be a hard and fast rule for the pluckers, *what is to be left* on the trees, whether 1 leaf, nearly at maturity, or more: this according to jāt, condition of the tree, elevation, weather, &c., will best be found out by the manager of the plantation, as no general rules can be laid down. I would be inclined to define *medium* plucking, as that which would give 20 per cent of orange and broken pekoe from the "bulk" with a No. 12 sieve, for that separation (the leaf having been machined, rolled, and fired, and the jāt a medium Assam hybrid). The lower grades of the remainder will then fall into ordinary proportion. To conclude:—This is my "stone to the cairn." Nothing new to add, as I agree with the majority of your correspondents who have preceded me on the subject.

1,600 TO 4,500 FT. ELEVATION.

LVI.

Yatiyantota, 20th May.

1. I cannot say if Mr. Armstrong is responsible for the statement, that the quality of tea is best when bushes flush most freely; but my experience of 7 years' manufacturing tea in the lowcountry points to exactly the reverse.

2. I have no actual figures to prove that application of manure improves flavor or strength of tea, but I am inclined to think it would do both, more especially the latter; at the same time I am not prepared to state that the cost of application of manure will compensate for the enhanced price which might be obtained for the teas from bushes so manured. In the experiment carried out on this estate, particulars of which appear in "Rutherford's Note Book," the object in view was more to obtain statistics as to yield than improvement in quality of tea.

3. This involves a large question; and to deal with it thoroughly would require an exhaustive treatise; my own opinion in as concise a form as possible is the following:—The main point after all is the balance sheet at end of year, showing profit for acre. I would deprecate very fine or very coarse plucking, the end to be achieved being to obtain the highest price for your teas compatible with placing them in the market as cheaply as possible. High-priced teas, as a rule, mean high cost per lb. of production, and low-priced teas the reverse. Hit the happy medium from which it will be found the largest profits accrue. As I may be misunderstood in what I have just written a little explanation is excusable. There are estates which owing to varying conditions will not produce as good teas as others: in these cases fair comparisons cannot be drawn. My remarks apply to estates working under parallel circumstances and having about same soil, jāt &c. You could name, Mr. Editor, and so could I, several properties in Ceylon, the teas from which at one period topped the market and have now dropped down to the average price: this is due apparently to one of two causes,—either their bushes have deteriorated, and cannot produce as good teas as formerly, or these gardens have found it more remunerative to produce an average-priced tea at a lower cost than a fancy (and necessarily small quantity) tea at a heavy cost per lb. I would express it as my opinion that the first of these two reasons is the cause.

In expressing the foregoing as the results of my own observations, which I may remark have been almost entirely confined to the lowcountry (Kelani Valley), I do not for a moment lay them down as infallible dictums, and am entirely adverse to drawing upon myself a heap of scathing or ungenerous criticisms; but simply as requested state what I have found to be the most paying method of "Tea Culture and Preparation." Your inquiries are certainly practical, and I trust my answers may be found the same.

F. T. T.

LVI.

Dikoya, 18th May 1889.

1. Provided the bushes are in a healthy condition, my opinion is that the quality of the tea is best from 6 to 12 months after pruning.

2. I am inclined to believe that manure does not improve the quality of the tea; there are knowing ones, however, who think differently, and those who can afford it should give it a trial.

3. Fair medium plucking will show the largest credit balance at the end of the year. R.

LVII.

Kotagala, 20th May.

1. It would, I think, be more correct to say that when the bushes are in good heart and other circumstances favourable, weather for withering etc., the quality of tea is best. After pruning or a long spell of wet warm weather (as at present) the bushes flush freely, but the quality of tea deteriorates.

2. It seems to be generally acknowledged that manure increases the quantity, and as far as my limited experience of manuring tea goes, it decidedly improves the strength especially when applied to poor or exhausted soils. If the manure applied is a plant food, and not a mere stimulant or "whip," I think this must follow as a natural sequence. I am strongly inclined to think that it improves the flavour also, though in a less degree. When the manure first begins to act and the growth is perhaps a little rank, it may have an opposite effect, but this would only be for a short time; and once the spurt was over and the tree settled down to steady work, I think the manure would help the flavour. I have made tea off a small field in the Kelani Valley, manured with a mixture of farmyard manure, factory sweepings etc., which had a flavour equal to and above the average of upcountry teas. The manure was forked in about 6 weeks after pruning and the leaf referred to plucked about 4 months after that.

3. In regard to this question, I agree with the writer of letter XXXVI, that it is only on specially favoured estates that a steady fine-flavoured tea is obtainable, however fine the plucking may be.

W. H. M.

P.S.—Whatever system is carried out, careful plucking is necessary to success.

LVIII.

1. I have always found that the tea bushes yield the finest tea, both as regards flavour and strength, after they have been allowed to grow up to what I may say, is their natural size, and before pruning and cutting down have been resorted to. The bushes then flush periodically, and better tea can't be got. How many young estates have "got their name up," by sending fine-flavoured teas, and were not these all manufactured before the trees were forced to flush by pruning?

2. I have no statistics regarding manuring, but am of opinion that it improves the strength of the tea.

3. I believe in medium plucking, *i.e.*, the bud, and a leaf and a half. If inferior teas are required, then another leaf. By flooding the market with inferior teas we may be doing the name of Ceylon tea much harm; but on the other hand our cheap Ceylon teas may be the means of ousting China teas.

T. (Elevation 5,000 ft.)

LIX.

Bentota, 20th May 1889.

1. I do not know whether Mr. Armstrong is responsible or not for the assertion that the quality of tea is best when the bushes flush most freely; but judging by the almost utter worthlessness of the tea manufactured immediately after pruning (the bushes flush freely then), I should think it was the other way on, and that tea from well-matured bushes flushing slowly in dry weather is more likely to give a superior article in both strength and flavour; however, nothing less than a proper analysis can settle this point.

2. Not having had any experience in manuring, I can't well answer this; but there can, I think, be no doubt about manure improving the strength, flavour and quantity, if the proper article is applied.

3. If one could only foretell what particular kind of tea would be in demand at stated periods we would

of course pluck fine or coarse to suit the market, but as matters stand, medium plucking, I think the safest. W. A. L.

LX.

Lauderdale, Rakwana.

1. With the exception of the 3 or 4 months after pruning, the best tea can no doubt be made when the bushes are flushing freely.

2. No.

3. Decidedly quantity as well as quality, medium plucking and careful manufacture will pay best in the long run. We must not go in for quality (*i.e.* fine teas) only, but endeavour to meet the China market with her own weapons and send in good lower grade teas as well. So long as we send in fine teas only, so long will they be bought to mix with China low teas (because cheap) to the barring of our own. Pour in lots of low grade tea as well as fine and the China teas will no longer be sought for, for ours will take the cake. Drive the China teas out, and there will be less chance of adulteration and a fair market for Ceylons; besides we shall win the freight to our own island which at present runs between China and London. Nil desperandum. R. S. D. T.

LXI.

Dimbula Estate, Kotagala, 20th May.

1. As a rule I do not think the best teas are made when bushes flush most freely, because at that time factories have a bigger rush of leaf than they can thoroughly well manage. The best teas in my opinion are made from bushes that have been pruned 9 to 12 months previously.

2. I have made very little tea separately from fields that have been manured: when I have it has always turned out well. I consider that judicious manuring should improve the strength of liquor, but quite think that repeated applications of manure may largely increase the yield, but at the same time to a certain extent spoil the quality of the leaf by forcing the bushes to an unnatural degree.

3. I always advise medium fine plucking, carefully done, which with due attention to manufacture should give a good tea combined with a good yield. J. R. H.

LXII.

1. I cannot answer the first question, even if I dared to.

2. In connection with the second question, I have a little experience tending towards an opposite conclusion. A field on this place was manured with white castor cake, a number of years ago. After the manure had begun to show effect, the leaf from that field was manufactured by itself and the tea made from it dispatched and sold in London separately. In price it averaged 0s 1½d less per lb., than the tea made during the same time from the other fields which had never been manured. The leaves were more fleshy than usual and withered very unevenly.

3. The answer to the third question seems very obvious. Of two good things no doubt "*both's best.*" But if we cannot have both to the full amount, then we have to consider what proportions of each are best. However, on this place since we began plucking all round once a week, a number of years ago, instead of once in ten or eleven days, as in former years, the crops have not been reduced in quantity by that. A small reduction in quantity has been made, but it has been entirely in the plucking of the primary flushes from which at the same time I began to take only the bud and one leaf the primary flush being too inferior in quality to allow of taking another or coarser leaf with advantage. These two changes, but mainly the weekly plucking, raised the average price of our tea from 1s 2d or 1s 3d to 2s per lb., and of course increased the profits in a far larger proportion. So far at least it would seem that if we can pluck finer by plucking over the fields within shorter periods we may leave quantity to take care of itself. There is a limit to this of course practically, but although plucking be the heaviest item of expenditure a considerable increase to that alone does

not much increase the cost of working the estate and putting the tea in the market. A very small increase in the selling price of the tea would more than cover this.

AN OLD TEA HAND.

LXIII.

The best teas produced in the Kalutara district are from July to the end of the year and the worst in the driest weather, viz. February and March.

When the heaviest pluckings are got the quality of the leaf is certainly not of the best; and in addition to the liquor being poor the same attention cannot be given to the curing of the tea as when a more moderate plucking is got.

Manuring with bulky manure increased the quantity largely and improved the quality considerably.

Medium plucking pays best I believe, and I think that if we all went in for fine plucking the tea produced would be used for mixing with China teas instead of as at present with ordinary plucking driving these China teas out of the market.

In a table published by a contemporary giving the cost of producing tea from crops of 150-500 lb. per acre, a mistake has occurred in the first column. The cost of production of 150 lb. per acre should be 56½ cents per lb., not 50 cents as put down.

The cost of producing 250 lb. per acre, which is about the average crop of several old estates up-country I know of, is put down at 40 cents per lb.; add to this interest on capital invested, say R250 per acre at 8 per cent, and the cost of production is increased to 48 cents per lb. At present prices I doubt whether 48 cents is being realized, and it behoves us all to give our best support to any scheme for opening new markets.

LXIV.

Dikoya, 26th May 1889.

1 I consider the best teas are made in the wet weather, say from June to September, and when the bushes are 6 to 8 months old from pruning. The worst teas are made during the hot weather from December to April, the flushes then are very quick in growing, and as a rule teas turn out thin and without any flavour.

2 Have had but little experience, but should think bulk and artificial would increase yield; cannot see how manure could affect flavour.

3 Certainly, and consider those who combine quantity with quality are doing far more to strengthen our market than by sending in strong flavoured teas which are used largely for mixing with weak China teas and so force their sale. Supposing everyone went in for fine plucking, query, would not the prices fall just as rapidly as they are now doing, and I should think the stronger the teas the less will be required. I quite agree with "W. F. L." in all his remarks, and his figures are pretty conclusive. S.

LXV.

1. It stands to reason that bushes must yield their finest quality when in their prime, i. e. just after "that first budding spring of youth," or 6 to 12 months from pruning; and the less the amount of foliage the stronger will the quality naturally be, provided always that a healthy leaf or shoulder be left, and not a goat-browsed-like nondescript, which is sometimes—or oftentimes?—seen. I have observed that flavour is much superior in the dry months.

2. A sample of unmanured tea tasted against one of bone and castor caked from the same field gave a slightly minor pungency.

3. It is the old story: *Est modus in rebus*, and he who hits the happy one will be happy.

P.S.—There have been some dull things written to your paper lately about tea, showing intensely the one-sidedness of thought. One absurd deduction you nullified with your usual incisive Ed. C. O. To two other statements I would make short replies. One was to the effect that tennis was incompatible with good teamaking. To this I would say: it is not the planter that works, but the planter who gets the work done, that succeeds. If a man has four or five hundred—ay, or even two hundred—acres to look after,

can he be in the factory all day? In that case, as far as actual teamaking is concerned, what is the difference whether he is absent at other works or—tennis? Again, to the statement that without carefully plucked leaf one cannot make good tea, I would ask: how is it that factories buying from four to six estates (I can name them—and leaf to sell is—well, not so nicely plucked as leaf to make):—do make good tea? A. V. R.

THE BANDIKAI.

Colombo, 24th April 1889.

DEAR SIR,—With reference to the valuable information which has appeared in your paper *re* the Bandikai plant and its fibrous qualities, I hope that the following extract may prove of interest. I have taken it from a book in the Colombo Museum Library on the "Fibrous Plants of India" by Dr. Forbes Royle, M.D., F.R.S., London, 1855.—Yours faithfully, G. A. J.

Extract referred to.

OTHER MALVACEOUS FIBRE-YIELDING PLANTS.

"In connexion with *Hibiscus cannabinus* we may appropriately mention the other fibre-yielding species of the same genus. Among these we find those which are also used as articles of diet; as for instance:—

"*Hibiscus esculentus*, the Okhro of the West Indies, with which is now united the *H. longifolius* of the East Indies, the *Bandikai* of Madras, the *Ram turai* and *Dheerros* of Bengal; and from both of which the Bammia of the West Coast of Africa probably does not differ essentially. Of all these, the long, young pyramidal pods are filled when green, with a large proportion of mucilage, on which account they are gathered when green, and cooked as vegetables, being much esteemed by many, though considered too viscid by others. The fruit is also used to thicken soups in the countries where it is indigenous and in the South of France and in the Levant. The seeds which may also be added like barley to soups, and have been recommended to be roasted as a substitute for coffee, * * * * *. The bark of this plant also abounds in fibre, which is of fine quality, as in many others of the same genus. Dr. Roxburgh cut the stems when the seed was ripe, and committed them to the steep a few days after."

The comparative strength of different fibres, amongst them those of *H. esculentus* are given in a tabulated form on page 268 of Dr. Royle's book.

WHAT IS SOJA BEAN.

To the Editor of the "Ceylon Observer."

DEAR SIR,—Something good to agriculture always comes from the Celestial Empire, and if any of your readers could tell us what they know of *Dolichos soja*, a spice which is now becoming very valuable in some parts of the world, they would indeed be doing another good thing to Ceylon planters. It is known in the Straits as "Soja Bean," and is said to be cultivated in Japan and China. I suspect it must be growing in Ceylon and known to the native; but who could say what is its native name?

NEW PRODUCTS.

(From "Treasury of Botany.")

SOJA (OR SOYA) *hispida* is the only representative of a genus of *Leyquinose* of the tribe *Papilionaceae*, and much cultivated in tropical Asia on account of its beans, which are used for preparing a well-known brown and slightly salt sauce (Soy), used both in Asia and Europe for flavouring certain dishes, especially beef, and supposed to favour digestion. Of late it has been cultivated as an oil-plant. *S. hispida* is an erect hairy herb, with trifoliate leaves, and axillary racemose flowers, which have a five-cleft calyx, a papilionaceous corolla, ten diadelphous stamens, and

an oblong pod which contains from two to five ovate compressed seeds. Modern botanists generally refer the plant to Glycine; which see.—B. S.

(From "Simmond's Tropical Agriculture".)

That well-known sauce, Soy, is made in some parts of the East, from a species of the Dolichos bean (*Soja hispida*), which grows in China and Japan. In Java it is procured from the *Phaseolus radiatus*. The beans are boiled soft, with wheat or barley of equal quantities, and left for three months to ferment; salt and water are then added, when the liquor is pressed and strained. Good soy is agreeable when a few years old; the Japan soy is superior to the Chinese. Large quantities are shipped for England and America. The Dolichos bean is much cultivated in Japan, where various culinary articles are prepared from it; but the principal are a sort of butter, termed *mico*, and a pickle called *soja*.

SALT IN TROPICAL AGRICULTURE.

SALT—MANURIAL ALUE—AUTHORITIES—JUDICIOUS APPLICATION NECESSARY—TODDY-DRAWING—INCREASED YIELD—REASONS—FUMIGATION—CARBONIC ACID—HOW FUMIGATION COULD BE OF USE.

May 9th, 1889.

The last issue of your *T. A.* contains a good deal of information and discussion as regards the value of salt in agriculture. The value of salt in agriculture is a subject on which opinions differ to some extent at the present day. The opinions of chemists and practical men have been taken and suited to support both views, viz., of its being generally useful in cultivation; and of its only being useful only in special cases and greatly injurious in others. The former view is held mostly by practical men who deal directly in agriculture, and deserves attention. Any good thing beyond a certain limit cannot be useful, and such is the case with salt. It is beyond any doubt of salt being a hygroscopic substance, thereby absorbing moisture and other gases, a solvent which makes other materials useful, an insecticide which destroys the injurious insects and prevent them from attacking crops, a substance which removes sourness in soil and helps the growth of plants, and last not least an actual constituent of cultivated plants. With such a list to its credit salt cannot be otherwise but a useful substance for vegetation. If salt is found in sufficient quantity in soils, it is no use adding it to such lands. It is not the case with salt alone, but with any and every substance. If they be already present, it is useless to add them. But in the case of salt we should be particularly careful, as if we add more, instead of its being useless, it might prove to be injurious, unlike most other substances. Prof. J. J. Manley in an article written by him on the salt industry speaks of its manurial value as follows:—"It is also used as a manure for land, an ancient practice in vogue in Palestine and China more than 2000 years ago. At the present day there is still much questioning as to the use of salt as a manure which has arisen partly from ignorance as to its chemical action and from its injudicious application. The fact also that it is speedily destructive of weed when used in certain quantities has helped to keep up a prejudice against it. However, by scientific farmers its use is well recognized, and each year it seems that a larger quantity is being demanded for agricultural purposes." (The italics are mine to mark the popular ideas which have prejudiced its use.) The same authority cites that "200,000 tons of salt are annually used as manure in the United Kingdom. Apart from its value in regard to the improvement of soils, both physically and chemically, salt is generally spoken as a good fertilizer for root crops and cereals. Therefore an application of salt—especially to such a hardier tree as the coconut—in the inland districts where they haven't got much in the soil must be of very great use. The physical and chemical improvement of soils, which result from the application of salt, are marked in warm and dry soils. Prof. Wright-

son, while speaking about salt, says, as regards its beneficial action on sour soils "that it may be used with good effect in pastures which carry a coarse herbage." The cause of a coarse herbage is mainly due to a sourness of the soils, and we have a good deal of sour soils in Ceylon both in the form of some cultivated and neglected lowlands. The experiment is worth while a trial, and salt issued at a less price to bring such neglected lands into bearing. The application of salt should be judiciously done. Dr. Johnston advises applying it either as a top-dressing at the rate from one to five hundredweights per acre, or using it mixed with water in staking lime for application to lands. He says: "When applied to grain crops, common salt almost always increases the weight per bushel of the grain when reaped mixed with quicklime and put on the land it gives strength to straw."

Salt if judiciously applied to lands should form a good fertiliser to most of our inland soils. Whilst a few hundredweights of salt per acre would ensure increased crops, a ton if applied might instead of giving increased yield spoil the whole crop.

While speaking of salt principally, if we at all find it useful, we should look for good results to the inland districts.

Some of the coconut plantations in the coast between Kalutara and Galle are entirely devoted to the drawing of toddy, and those trees appear healthier than the rest. There was a question once whether toddy drawing increases the production of fruit, and your Siyane Korale correspondent had a given list of chemical analysis of the products of the tree. I myself have observed and agree with him that trees after toddy drawing produce better crops. It cannot be owing to any stimulating effect as mentioned in a note thereto; if so, the vigour of the tree would have to be sacrificed for the better crop, but it is not the case here. Trees which are devoted to toddy drawing, show forth a vigorous growth than the rest. It is a common belief amongst the goiyas, that coconut trees which do not produce well, would be improved by this process, and so they in many cases have resorted to the process of drawing sweet-toddy, more for the sake of improving the trees than for the syrup obtained. When we refer to the analysis of the products, we find this quite practicable, as a tree would not lose so much mineral matter when used for toddy drawing as from the ordinary way of cropping fruits. The amount of the yield of toddy per tree for one year is calculated at about 63 gallons, and the mineral matter containing in them would amount to nearly 1,155 grains, whilst the average produce of tree consumes nearly 12,204 grains of mineral matter, or nearly eleven times the quantity consumed by the toddy. So it is quite clear that a tree after being operated in this way for a year would consume only one-eleventh part of what is required to bear an ordinary crop. Hence the increase cannot be owing to any stimulating effect produced by toddy drawing, but actually by a process of great saving of mineral matter, a part of which goes to strengthen the tree and the rest in the plentiful production of fruit.

The question of fumigating coconut trees was brought before the notice of the public by "Old Planter" in one of your issues, and at the same time casting a slight on the Agricultural School on some hearsay information which was at once reputed by "O. D." putting to right the opinion of "Old Planter." The question is, has smoke to do anything at all in improving a coconut tree? It has no direct effect as some people believe in yielding more carbonic acid for plants. No person aspiring to know the scientific theories of plant life would ever believe; and it is like the same as the human voice theory. When we put aside the question of carbonic acid we find some uses resulting from this process. Fumigation acts in destroying a deal of fungi and insects which live upon the leaves. Apart from carbonic acid, smoke contains traces of ammonia, nitric acid, and water vapour which are absorbed by leaves forming a good plant food. These two reasons are in themselves enough to account for the action of fumigation on trees, and when the materials for the purpose is available, and is of no use in any other way, smoking would do well in improving trees. W. A. D. S.

AFFORESTATION IN CHINA.

The question of afforestation in China is at the present time attracting a great deal of attention. China is a treeless country, and to this, perhaps, are due the devastating floods which work such ruin there, and the fearful seasons of drought which are almost as destructive as the floods. The timber used in various ways is all imported—chiefly from the United States of America, and from Hainan and Formosa. Till the overflow of the Yellow River some time ago, no one paid the least attention to this question; but now a proclamation of the liberal Viceroy, Li Hung Chang, to the people of his thickly-populated provinces, shows that the subject will receive the attention it deserves. His Excellency says that one of the first principles in governing a State is to watch over the agriculture of the State, so that it may benefit both the individuals who till it and the State. In one of the provinces over which he rules—namely, that of Chili—arboriculture is rendered especially easy by the softness and fertility of its alluvial plains. If we omit the various species of fruit-trees, such as the apple, pear, and apricot, other kinds of trees are very rarely seen, and in consequence vast tracts of fertile plains are left barren. Some slight attempts have been made to plant these extensive tracts with forest trees; but the strong northerly winds which prevail soon uprooted trees which had not been planted to a sufficient depth nor in well-chosen places. Amongst the peasants, the Viceroy says, the principles of arboriculture are unknown, and therefore their previous efforts have only resulted in labour and money uselessly expended. In recent years the Viceroy has ordered the planting of willow-trees along the banks of the streams and rivers in Chili, with the object of protecting and strengthening the embankments.

If successful methods, His Excellency asks, have been found for cultivating trees in salt lands, how much more easy ought they to be found in the rich level plains of Chihli? Accordingly, the authorities of the various prefectures and sub-prefectures of Chihli are instructed to procure the necessary seed trees, and to inform the people in their respective districts of the eight directions for tree-planting and the ten benefits to be derived from the same. Steps are to be taken by the authorities to encourage the people in their efforts at planting, but official agents, who might oppress the people, are not to be sent among them. At the end of each year a statement is to be submitted to the authorities, by every person who has tried planting, of the number of trees he has received, the number successful, the species which have thriven best, &c., so that the Government may reward those who are most successful in these experiments in arboriculture, as well as gather information to guide them in the future. Instructions are given to the local authorities to deal severely with any person who steals or cuts down the trees of others. The Viceroy says that his intentions in issuing this proclamation are to afford another source of livelihood to the peasants, to help in preventing droughts and checking floods, to regulate the rainfall, and to beautify the country.

The eight directions and the ten benefits are worth recording. The directions are as follows:—(1) To fortify the roots against injury from cold, which, on account of the loose nature of the soil near the surface, readily injures the roots, a fertilizer, made by burning a mixture of dung and grass, should be used when planting trees, and when the fertilizer is put in, the roots should be carefully covered. (2) When a tree has been securely planted, a small cumulus of earth should be placed around it, 6 or 7 inches high, and should be renewed before winter sets in every year till the close of the third year. By this means the wind and cold cannot reach the roots, nor will the necessary natural nourishment in the earth escape. (3) In places exposed to high winds the trees should be planted to a depth of at least 3½ feet; at this depth the rich part of the soil is reached. In case of willows and other such trees,

the outspreading and dependent branches are to be carefully pruned. (4) Rich earth, with a suitable fertilizer, is to be added to poorer soils. (5) To prepare the ground the reception of the seeds of such trees as the oak, elm, poplar, cypress, &c., which are shed every year, a trough is to be dug round each tree and filled with water to keep the soil moist. (6) Willow and mulberry trees should be planted in the spring, when there is rain. Before planting the young shoots, the soil should be well loosened and fertilized, and grafting should always take place after rain, and the graft-trees should be well watered every alternate day. (7) In transplanting trees, the greatest care should be taken to preserve the three vertically-projecting roots, which every tree has, from the wind and sun. When there is rain, a small hole is to be dug by the side of the tree, cutting away one of these roots; this operation is to be repeated in a fortnight if there is rain; if not, a month must elapse before the second root is cut, and similarly in the case of the third root. When the roots are cut away, innumerable little roots will be thrown out. If there is no rain, the ground must be well watered before any transplanting is attempted. (8) In raising trees from the seeds of the oak, mulberry, &c., some fertile spot should be prepared just as it would be for a crop of grain, and the seeds are planted in the same way as grain is planted. Spring time is the best, and while there is rain. When the young trees spring up and grow to the height of one or two feet, they can easily be transplanted as directed above.

The ten benefits of planting trees are thus enumerated by His Excellency:—(1) By planting trees at the river-banks the loose and sandy soil is strengthened by the roots, and the banks increase in height. (2) a large and profitable industry will spring up if pine, elm, willow, &c., are planted in the mountains on the borders. (3) The planting of trees around fields and farms will do away with the superfluous moisture and preserve a fair equilibrium of wind and fluid influences. (4) Where trees are in abundance, droughts will be unknown. (5) Abundance of trees also help to ward off epidemics, and in thickly-populated districts trees should be especially planted for this purpose. (6) Where there is abundance of trees, travellers and families can find rest and shelter in the summer. (7) The operations of highwaymen and banditti are hindered where trees and forests are plentiful. (8) The snows on the mountains of the border will be absorbed by forests. (9) The poorer peasants will have sufficient fuel from the branches, which are pruned every year. (10) Many of these trees, as the *Quercus mongolica*, afford food to the silk-worm, which, in the mountainous regions, weaves a cocoon which makes much cheaper and more durable silk than that of the mulberry silk-worm.—*Nature*.

SWIETENIA MACROPHYLLA.—Attention was directed to a reference in the *Indian Forester* of the current month to this species of mahogany, of which beautiful avenues have been formed in the Royal Botanic Gardens in Calcutta. The seeds were sent to Calcutta by the India Office in 1872, and were said to have been collected in Honduras; but as soon as the seedlings were a few inches high it was seen that they were different from those of the true mahogany. In their twelfth year many of them had reached a height of 20 feet, and had begun to flower freely; and in 1885, their thirteenth year, they yielded capsules containing good seed, thus presenting a marked contrast to the true mahogany, which does not seed until it is forty or fifty years old, and then but sparingly. It is believed that the wood has a rather higher colour than that of *Swietenia Mahagoni* “but the quick growth of the new species, and its habit of producing good seed in quantity, make it a desirable species to cultivate.”—*Proceedings of A.-H. Society of Madras*.

Correspondence.

To the Editor.

BLACK WATTLE—*ACACIA DECURRENS*,
VARIETY, *MOLLISSIMA*.

DEAR SIR,—I find Haldane's and Spon's figures for black wattle so different from the results derived by you from Mr. Tringham's experiment, that their figures may be of interest as suggesting where further information is required upon the cultivation of black wattle if undertaken on an extensive scale.

Haldane, in his "Sub-tropical Cultivations," recommends that the black wattle should be planted 6x6 ft. apart, or 1,210 trees to the acre; and he says the bark should be harvested in from 5 to 10 years: the older the trees, the more valuable being the bark. The proceeds of an acre he estimates as follows:—

From $\frac{1}{3}$ of an acre in 5th year 2 $\frac{1}{2}$ tons @ £5 a ton, less for stripping £1 a ton, baling 10s, carriage £1 and cutting 10s	...	£5 0 0
From $\frac{1}{3}$ acre in 6 years, 3 $\frac{1}{2}$ tons less as above	...	7 0 0
From $\frac{1}{3}$ acre in 8th year, 4 $\frac{1}{2}$ tons less as above	...	9 0 0
		£21 0 0

From which deducting original price of land in Australia and New Zealand and planting and cultivating expenses £6, we have £15 an acre as the net profit in 8 years + the fenced land and value of timber. Mr. Haldane admits that his is a low estimate, the usual estimated net profit being £25 an acre at the end of the 8 years.

Spon's Encyclopædia gives in some respect a more detailed estimate of expenditure and receipts for a plantation of 100 acres planted 10 ft. apart or about 400 trees to the acre:—

Rent of 100 acres, 8 years @ 6s per acre per annum	...	£240 0 0
Ploughing 100 acres a drill 10 ft. apart	...	25 0 0
Sowing and actual cultivation and seed	...	37 10 0
Supervision for 8 years @ £10 per annum	...	80 0 0
Pruning	...	50 0 0
Incidentals	...	27 10 0
Interest on whole amount expended during 8 years	...	240 0 0
Shipping 15s per ton, cutting 10s	...	1,515 0 0
		2,215 0 0
Yield 6 years $\frac{1}{3}$ of 400 trees @ 56 lb. bark 332 tons.		
" 7 " " say 68 " " 400 "		
" 8 " " say 80 " " 480 "		
		1,212 @ £4 4,862 0 0
Profit on 100 acres in 8 years	...	£2,637 0 0

The values given by both Haldane and Spon appear to be average net values after deducting freight, shipping, and London charges, for Spon states London values to be £5 to £9 10s for long bark and £5 to £12 chopped.

The age at which the trees come to maturity for stripping is you will notice in both the above estimates given at 5 to 8 years as against 3 $\frac{1}{2}$ of Mr. Tringham's experiment; and the number of trees to the acre instead of being 2,720 trees is in one estimate 1,210 trees, with similar yield per tree to Mr. Tringham's 3 $\frac{1}{2}$ year old, and in the other only 400 trees, yielding, however, nearly treble the amount per tree. Does the extent of Mr. Tringham's experiment show that the trees may be planted as close as 4 ft. apart on a large acreage. I fear even 6 ft. apart will be found too close when a plantation is covered at such distances.

Spon says the wattle bark is obtainable in vast abundance. But the export from Australia and Tasmania have fallen from 18,000 tons in 1876 to 9,500 in 1880. Would this not show that the demand for wattle bark is limited? In any case oversupply is sure to reduce the London value to be a £5 per ton, and it would be prudent to take this as gross value from which will have

to be deducted freight and London charges. Myrobalans have dropped from £5 14s per cwt. in 1880 to £5 8s 6d in 1889.

Black wattle wood is said to be valuable for cask-staves, wheel-spokes, and fence-rails; but it is evident the trees will require to be well matured before the timber can be utilized for any other purpose than firewood. Black wattle should make an excellent and valuable fence, planted 4 ft. apart in drill rows, and this may be the most prudent limit of cultivation. Will it grow in the lowcountry?—Yours,
J. D. V.

WINDMILLS WORKED TO DRIVE A COFFEE PULPER IN OLDEN DAYS IN UVA.

Uva, 30th May 1889.

DEAR SIR,—Just a line to say regarding windmills. I erected two, both perfectly successful, when there was wind and simple and easy to construct. One was on the horizontal principle; the other vertical, neither required to be turned to the wind, but worked with the wind in any direction. I used them to work hand pulpers, shipping the pulper handles when there was no wind or insufficient. Either could have worked a pump easily, so as to fill a reservoir or raise water for any purpose.—Yours very truly,

OLD OUVAH.

"ACACIA DECURRENS" FOR TANNING BARK.

Elephant Nook, 30th May 1889.

DEAR SIR,—With reference to your footnote to my last letter, I restricted the calculation to expenses incurred after the delivery of the bark at the upcountry railway station; and (if I am correct in estimating the costs of transport, home and local charges &c. to be the same on *A. decurrens* bark that they are on cinchona bark) showed conclusively I think that the proceeds of a ton of such bark as I despatched would cover the expenses referred to, but leave no appreciable margin to set against cultivation and charges previous to the delivery at railway station.

In reply to your question as to the quantity sent for valuation: the parcel weighed 44 lb. and was taken from two trees,—one large and one small—felled for the purpose. It included portions of the bark of all parts of the tree excepting small branches, and it is most important that this should not be overlooked, for the Secretary to the Colombo Commercial Co., Ltd., London, wrote: "The old bark should be shipped and not the new." What the result of the analysis and valuation would have been had the sample been of old bark only is unknown; the analysis 34 $\frac{35}{100}$ per cent of tannin, and valuation £10 to £11 per ton, and the yield of $\frac{1}{2}$ cwt. per tree were for the mixed bark, old and new.

On the other hand, after looking through the *T. A.*, I find 40 per cent of tannin the maximum given for bark of *Acacia decurrens*; and the most valuable bark (*Acacia pycnantha*) is quoted as giving up to 47 per cent. But while *A. decurrens* gives up to 500 lb. of bark per tree, the maximum for *A. pycnantha* is given at 70 lb. only. (See *T. A.*, 1884-5, page 165.)

I measured a tree (*A. decurrens*) standing on the Military Reserve here the other day, and found it at 2 feet from the ground over 6 feet in girth: the height of the tree is between 50 and 60 feet, with wide-spreading branches 20 feet in length. But I have never yet seen a tree of this variety without shoots to the root, and understood that it was from its habit of spreading from the roots that it derived its name. I feel certain that the tree your Maskeliya correspondent refers to is not

A. decurrens. I should not think that the wood of *A. decurrens* would be of any value excepting for fuel, certainly very young trees were not. From the bark, when wounded, exudes a gum well suited for office purposes; I use no other. Messrs. Piesse & Lubin manufacture a scent from the blossom. A fluid extract of the bark was sold in London for £50 per ton a few years ago.

My experiment was on too small a scale altogether, to be taken as conclusive that the cultivation will not pay. My trees were planted as a breakwind to shelter cinchona on an exposed ridge, a purpose they answered well. The cinchona being replaced by tea, the shelter was not needed, and the spreading roots rendered the tea for a chain below and 40 feet above unprofitable. A ditch 2' by 1½' below which they were planted merely checked the spread of the roots for a short time: consequently on receipt of the valuation I felled and burnt the lot.

To those wishing for further information I would refer them to the reports by Mr. J. E. Brown, Conservator of Forests, to the Legislative Council in Adelaide, in the *T. A.* 1884-5 (pages 165 and 916). I enclose two or three leaves of *A. pycnantha*, the true golden wattle, taken from the Local Board nursery. I think this will convince you that Mr. Nock was right when he expressed doubts as to there being any of this variety in Nuwara Eliya.*—Yours faithfully,

WALTER R. TRINGHAM.

P.S.—German oak barks give 13 to 16 per cent of tannin only.—W. R. T.

THE NEED OF MAKING "OOLONGS" AND SOME CONGOU TEA IN CEYLON—OF SUITING AND MEETING THE DEMAND: ENCOURAGING ESTIMATES.

30th May 1889.

DEAR SIR,—I am sorry to see the cold water thrown by the press generally upon the proposed production of oolongs in Ceylon, as, if we are to command the tea market in both America and the Greater Britain, it will not be done by confining our attention to one description of tea only, nor by producing only the finer qualities of black tea. It is depressing to anyone believing, as most of us I hope do, in our capability of producing teas of all qualities at as low a rate as our neighbours in India or elsewhere, to see the outcry raised by correspondents when prices fall to below 10d; as we must be prepared to see them fall still lower before any permanent improvement can take place. It seems to be admitted that we cannot place congou at anything near the price of China teas of that class, *i.e.*, 4½d, in London; but I think it will be found on examination, that, although an average of 4½d would be ruinous, a proportion of from 12 per cent to 20 per cent of the total yield of a tea estate can be sold at this figure, and that notwithstanding a small profit per acre can be made. I doubt if the Chinese who sell congou at 4½d make money on that particular grade, though they may make a profit on their general average of about 8d, as many Ceylon estates would pay fairly well at the same figure. The average yield per acre in Ceylon of tea in full bearing is generally, I think, taken at 300 lb per acre: this average yield at low rates should give a fair interest on the money invested, and taking Ceylon as a whole the tea enterprise may be said to be in a sound state as long as our average does not fall below 9d. That many estates giving large yields and favourably situated as regards Sinhalese labour and other advantages would pay handsomely

* Certainly the leaves sent are very different to any we have seen on trees in Nuwara Eliya.—Ed.

at even lower figures, is probably known; but in looking at the enterprise as a whole 9d may be taken as about the lowest remunerative price for our teas, though prices would have to fall below 8d before a loss was made on working expenses. The question may be asked as to whether it is to our interest to produce and sell congous at as low a price as 5d. If we were the only producers it would obviously not be so, but as if we do not ship cheap congous others will do so, and our not shipping merely keeps up the price of these teas and encourages other countries to continue producing them; it is probably better for us to ship a proportion of congous, with a view to displacing these other producers. Anyone looking at the Indian and Java price lists will see that either these countries can produce teas at a less average cost than a portion of the Ceylon estates, or must be working at a loss. We shall probably not know for some time what is really the case, and in the meantime must do our best to produce sound teas of all qualities at as low a figure as possible, bearing in mind that to restrict production would be but to leave an opening for other countries, who would not follow our example, and that, though temporarily relieving the market, the quantity short manufactured by our only making say, high-class teas would soon be supplied by India or Java. If, as seems to be conceded, we can produce Oolongs of good quality, the press and public generally should support the attempt. It would be taking some of our eggs at any rate out of the black tea basket, and if Oolongs were made on any large proportion of Ceylon estates, it would prevent our outturn of black teas assuming the gigantic proportions it seems likely to do in a few years. The attitude at present taken is worthy of the British manufacturers, who, on receiving orders for axes and other tools of a particular pattern for the East, refused to execute it, saying that their ordinary patterns were superior to those wanted and they could have them or go without; naturally enough the orders went to the Continent, where manufacturers were found more accommodating, and a large section of trade was lost to the too conservative British manufacturers, nor did they get much sympathy. It must be remembered that if we will not make Oolongs there are others who will, and that if the American want Oolongs and prefer them they will have them (and why not?); they cannot be expected to take to black teas to suit our convenience. The market for Oolongs is ready and does not want educating, and it would enable the Ceylon-American Co. to operate with a better chance of success from the very beginning if they could supply Ceylon Oolongs either as a blend with our ordinary teas or by itself. If as a blend it would gradually instil a taste for our ordinary teas, but if we produce Oolongs in any quantity it will be immaterial to us which kind they buy, provided it is produced in Ceylon. After all it is a matter of "Will it pay?" and from what I hear of some estates making Oolongs and selling them at very remunerative prices, wisely saying nothing about it, I have no doubt Ceylon Oolongs will pay very well.—Yours truly,

SABARAGAMUWA.

THE FIRST PRIZE TEA AT THE KANDY SHOW; REVISED PLUCKING.

Brunswick, May 31st, 1889.

DEAR SIR,—In reply to your correspondent "Inquirer," and for the information of others I annex a copy of breaks of tea from which the "gold medal" tea samples were drawn, which was the quantity of all tea made on Brunswick from 24th April up to the 18th May last, and will be shipped in a few days, marked "Gold Medal 1889," so that the public will be able to see how it sells. I would suggest that "Del Rey" and "Hoolan-kande" do publish their breaks and ship their Exhibition tea, with special marks too, so that the test of the London market may also (I hope) confirm the opinion of the judges at the Kandy Show.

I may add further that since the 24th of April I have been plucking $\frac{3}{4}$ of a leaf finer than I ever did before, and my present system is two leaves and the tip, leaving one whole leaf and the *dummy*, and going round the estate from 8 to 10 days plucking.—Yours faithfully, A. E. WRIGHT.

COTTON CULTIVATION IN CEYLON.

DEAR SIR,—Herewith I send you copy of article on cotton caterpillars taken from *Planting Register* of 29th August 1872, not 1887 as your printer made it,* which I consider useful information for my fellow planters at the present time. Planters have not the money to spare to cultivate what does not pay them, and I firmly believe from the trial Dr. Duke and I gave to cotton cultivation it will not pay. If Mr. Blackett will be good enough to give us an account of what it cost him for seed, planting, attending and harvesting his cotton and amount realized for the cotton and seed, latter should be valued as to what it would be sold for as cattle food or manure, not as seed cotton for planting, then planters can have the latest test on a fair scale.

It has been said you can plant cotton between young tea; no doubt you can, but at what cost

to the young tea. Cotton seed I saw mentioned the other day as nutritious food for cattle and good manure; so it is; test or analyse your soil before you plant your cotton, then again after you have taken off your crop, and you will not grow cotton at the expense of weakening your tea.

I held from the first that Cearà rubber and Liberian coffee would not pay to cultivate in Ceylon for simple reasons:—(1) Rubber requires a moist and fairly good soil (we were told to grow it on ridges and poor patches of coffee); (2) Liberian coffee requires a deep rich soil, of which we had no more as our best land was already planted with Arabian coffee; (3) there were other products paying us better than rubber; and (4) we were not allowed to give Liberian coffee that assistance with manure which it required, to say nothing about its being subject to attacks of leaf disease and bug as much as Arabian coffee.

What has been our fault? When our coffee was first attacked with leaf disease, why was it not properly treated at once? Pruning, manuring, forking soil, disinfecting both bushes and soil was *all* that was required and I have proved it. Bug same: the only additional treatment for the latter is to keep the stem of the tree free of decaying bark, moss &c., their hidingplace and passage to the roots.

Our coffee was weakened by planting cinchona, pruning and manuring neglected; strong remedies, carbolic acid powder, coral lime and sulphur, applied which did more harm than good; what is strong enough to kill the insect is also strong enough to damage young wood.

There was a rush for tea, everything had to make room for tea, the first in the field no doubt made a handsome profit, getting high prices for their tea and seed; anyone writing in favour of coffee (trying to stop the wholesale destruction) or of cutting out cacao was called a maniac, a lot of land unsuitable for tea cultivation without assistance was planted; the required assistance not being given, tea proves unprofitable, but who is to blame? Find out what is deficient in your soil, give it in time, make your roots and bushes strong, and you will find tea will pay even at 6c per lb. in Colombo.

Palace for factory, waste of machinery avoid; see to careful pruning at the proper time; give good supervision to your plucking; proper nourishment on old estates where surface soil is poor, especially when plants are young; if crippled in their youth for the want of some nourishment the plant will often never make a good bush.

In my last letter your printer made me say, come and see Maria estate cacao, Raxawa tea and cinchona, Wategamawatte cacao and coffee, "*and in which*:" these last three words should have been "*all of which*," were old abandoned native gardens once; please correct same if reprinted.

Cacao on some estates in this neighbourhood elsewhere was cut out or shade out down and tea planted; whereas if assistance had been given to the cacao in time with water-holes, forking, manure, more shade planted, the large shade trees thinned out by cutting out some of the branches, the surface roots cut away, and pepper, vanilla, or betel planted to run on the shade trees, how profitable these properties might now be; whereas coffee and cacao are gone, tea is left struggling for existence, no assistance given. What little coffee and cacao is left on these properties have given fair crops last year.

More power must be given to the superintendents who are on the spot and must know best what is required and when. "A stitch in time saves nine." know there are many good superintendents in eylon who could show good results if they were ble to carry out their wishes in cultivation; it is

* J. H.'s mistake, not the printer's.—Ed.

their duty and wish to work estates as cheaply as possible consistent with good work.

You often hear good manure condemned, because it was applied where it did more injury than good; take the same manure to another soil where it is required and see the result. Lime, as a rule, is condemned in tea, yet there is some soil where lime is required even for tea. This I have proved on a small scale on Maria and on a larger scale on Raxawa; it is only the other day I was told by the present superintendent of Raxawa that a planter from Kelani Velle had pronounced that field as fine a one of tea as any they had.

Let the captain of the ship (planter on the estate) stay at the helm (have the power to act), and the ship will be brought safe and sound through breakers to a smooth harbour and the estates carefully worked will not feel the depression of prices &c.,—
Yours truly,
J. HOLLOWAY.

(From "Planting Register" 29th August 1872.)

THE COTTON CATERPILLAR.

A week or two ago it was not uncommon for one to ask another in Lahore, "Have you heard the news?" The news being a scrap from Reuter to the effect that the "cotton caterpillar had appeared in the Gulf States." Those who laughed at the apparent want of importance in the telegram were not aware of the whole import of the words, for they implied the possibility of an utter failure of the American crop and an immense impulse to Indian trade and, we may, add, to local cotton growing. This being the case a few facts regarding the destructive pest which was important enough to deserve the telegram may prove acceptable. The entire cotton crop of the United States was destroyed by the "Army Worm" (as this caterpillar, the larva of a moth, *Heliothis Armigera*, is called in America) in 1788, 1800, 1825 and 1845; it also did serious damage in 1866, chiefly in Louisiana, it has altogether appeared 23 times in the United States since 1793, the year of the greatest devastation having been 1825 when barely enough cotton to afford seed for the ensuing year escaped its ravages. In 1788 these insects destroyed 280 tons of cotton in the Bahamas; they caused the cultivation of cotton to be abandoned in many of the West Indian Islands and the case was almost the same in Egypt. The Army Worm appears often in Guiana and other parts of South America. The mischief done by these creatures is fortunately not always of the same serious extent; sometimes, even the insects, when they come late as they did in 1865, thin the seed pods, and produce a positive benefit. If it were not so, considering the 23rd recorded visitations, the growing of cotton would be too hazardous to be continued. The most favourable circumstances for the production of the Army Worm are heat, moisture, and clouded skies, up to the end of June: when such is the case the visitation is regarded as certain. The caterpillar cannot support great heat and continued drought, a terribl summer kills them. The caterpillar is yellow with a brown stripe down the back. *Heliothis Armigera* is also found in England, but does not commonly occur.

COTTON-GROWING IN THE EASTERN DISTRICTS: HOW IT WAS KILLED OUT.

Colombo, 4th June 1889.

SIR,—Now that the attention of the Government and the general community has been drawn to cotton as an industry which may turn out a profitable one, I think it is time something should be done to effect the revival of its cultivation amongst the poor half-starved inhabitants of the Binenna Wedirata. It does not seem to be generally known that up to 1876 or 1877 a very considerable quantity of cotton was grown and woven into very serviceable material, by the natives of that part of the country. In Wellassa, the Park country

round Nilgala, and from thence down to Batticaloa and indeed, I believe, throughout the whole of that part of the Wann, weaving looms for home-grown cotton were common at that time, though at Batticaloa and the immediately adjacent districts it had been found both cheaper and more convenient to import cotton yarn for the purpose. Between Batticaloa and Trincomalee along the coast road it was by no means uncommon to find supplies of raw cotton stored up for weaving purposes, and the clothing—such as it was—of the semi-savage people of the interior was of home manufacture. Unfortunately for these poor people some fifteen years ago, when the demand for Crown land was so great and the Government had begun to look about and talk of reserves and so on, amongst other matters the regulation of chena cultivation was taken in hand. Totally oblivious of the vast difference in the conditions under which valuable forest land in the hills was devastated for the growth of kurakkan, &c. &c., and those under which the dry thorny jungles of the lowcountry were made to yield a little profit to the natives and which was unavailable for Europeans, the enactments relating to chena lands were made applicable to both alike. The restrictions thus placed upon obtaining land for the growth of cotton were so great, and the loss of time and money so heavy, with considerable trouble in applying first to the Arachchi and then to the Ratamahatmaya, and the Assistant Government Agent, and the Forester, with the number of applications, and reports and replies, and forms, and stamps and bribes, which were entailed on the endeavour to get leave to cultivate any particular spot of ground, all became so burdensome and intricate that in a very short time many—nay most—of the natives gave it up in despair. In this way the industry was virtually wiped out, and this the only industry—apart from the precarious cultivation of food—which was open to the natives of those barren thorny wastes from which no European could extract even the barest of subsistence. The endeavour to preserve for the use of the Crown a few acres of jungle in the planting districts was thus the means of actually destroying an indigenous industry in other distant parts of the island, which had there existed from time immemorial. Old Kandyan 30 years ago told me they well recollected the time when at yearly intervals bands of armed men from Kotmale and Dimbula were accustomed to go down to the Wann and purchase the cloth woven there, and which was the best they could obtain in the country.

After traversing that part of the country (in 1877 I think) and seeing for myself what was going on, I not only published in the papers a relation of what I had seen, but I pointed out to the Government Agents the hardships entailed upon the natives by the new measures relating to chena cultivation. The authorities quite saw this, but they all agreed that unless special regulations were made for that part of the country nothing could be done; and, as far as I can learn now, nothing has been done; and unless the country has been altogether depopulated since my visit, some step should be taken to aid the people in reviving the old industry. It seems anomalous—to say the least—that the Government should be assisting both Europeans and natives in the Western and Central Provinces in the cultivation of cotton, when it has actually destroyed the same industry in the Eastern Province, and does nothing towards its revivification. Within the last few days I have heard of the cotton plants being still existent in Butala and Wellassa,—and it would be compara-

tively easy to make a commencement in reviving their cultivation by removing,—in that part of the country,—the restrictions on chena cultivation under certain conditions, and by letting the natives have such land as they require free of taxes for a year or two. At the same time the headmen must be given to understand they will be expected to persuade the natives to return to their old employment of spinning and weaving. It would be but scant justice were this done and done at once.

I may mention that not very many years since cotton was growing wild in the neighbourhood of Hambantota, propagating itself year by year from plants originally cultivated in the experimental Gardens which were tried there a long time ago.—Yours faithfully, EDMUND WOODHOUSE.

COTTON CULTIVATION BY THE PLANTERS IN CEYLON:—No. 1.

DEAR SIR,—At the risk of being accused of crying up "nothing like leather," permit me a few further remarks on cotton cultivation. One might feel inclined to sympathize with Mr. Holloway's first unsuccessful attempt, but his feeble wail of despondency, his hysterical demand for a reprint of the difficulties of others, his hasty conclusion that cotton will not pay, can only excite painful surprise. It is not in this spirit that the Ceylon planter is accustomed to wrestle with a new product. Probably no product suffers more from pests, large and small, than cacao, but wherever the locality is suitable and the planter's work good, then cacao thrives and pays well. If however, the cacao planter like Mr. Holloway, had contented himself with merely sending his moan to the papers and then giving in, he would soon have found his boot on the other leg. Let Mr. Holloway indulge himself if he will in idle day-dreams of his defunct coffee, but let him modestly abstain from such hasty generalizations as that cotton will not pay in Ceylon.

Of course if a man plants in poor land, he must expect poor crops. If in a windy place, his bushes will be battered and his pods scattered in times of storm. If in a very wet climate, much of his crop must stick during the rains. If planted at stake a certain percentage must fail. If grown in the hot, moist portions of the country, insect pests will be troublesome. But it is satisfactory to know in spite of Mr. Holloway that cotton is adapted for a large portion of Ceylon, that its cultivation need cost but little, that returns are quick, that prices are good, and that whatever this colony may do, the market is practically unlimited. It is true that like all other vegetable products, it is troubled with insect pests, but so far as my limited experience goes, these can be fought, and fought successfully, not from one's desk, but by frequent personal inspection. I have a splendid little field of sea island cotton of about six acres, planted last year. The plants are now strong, healthy bushes covered with crop in all stages, and after some little careful but inexpensive cultivation, I could not this evening find a single red bug. I have no intention of gratifying Mr. Holloway's curiosity as to the figures in my ledger, but knowing the small expense I have incurred, seeing the crop, and aware that even now in these times of low prices, Sea Island cotton ranges in price at home at from 1s to 1s 9d per lb., I am quite satisfied with my prospects in cotton.

So far it would appear that the Sea Island cotton is the best variety for European enterprise. It is reputed the more delicate, but it responds to good cultivation, it is a perennial, the scion is easily cleaned, its value is very high,

the seed is better for cattle, and I have found it a quick and free bearer. For native cultivation probably the kidney or rata-kapu would prove the best. If not actually indigenous it has become thoroughly acclimatized, it is very hardy, and will stand much neglect, while the cotton is of fine quality and would be gladly purchased locally by the Colombo Spinning Mills.

It may be asked what is Government doing to foster the beginnings of a great cultivation? What broad liberal views are they taking of the future? I am afraid little more than an absurdly managed experimental field at Mahara and the offer of free seed to the natives. With the gradual decadence of coffee and the possibility of tea falling to a non-paying point, there is small hope for Uva and its extravagant railway, save by the general cultivation of some such product as cotton:

1. The headmen ought to be plainly told that their offices and honors depend on the extension of native cultivation amongst the villagers.

2. Village roads should be freely improved and extended.

3. The carriage of cotton by the railway should, as a new product bringing new traffic, be for a time at least at third class rates.

4. Crown chenas should be rented out on some liberal and intelligent system.

5. Seed should be supplied, not free, but at a nominal price afterwards recoverable.

6. And such other encouragements as may seem good to the powers-that-be.

A. G. K. BORRON.

NO. 2:—MR. BLACKETT'S COTTON EXPERIMENT.

Doteloya, Aranayaka, 8th June 1889.

DEAR SIR,—I noticed your remarks about my Jack Tree Hill cotton in your paper of the 4th instant, and I am sorry I cannot give you any further particulars of cost &c. yet.

I had to give up ginning with the little wooden gins as it was such slow and expensive work, but thanks to Messrs. Dariey, Butler & Co., who took the trouble to get a gin over from Tuticorin, the ginning is being done by those gentlemen for me just now. I hope to get all the cotton away from Jack Tree Hill very soon and have it shipped, and soon after I shall have much pleasure in giving full particulars through the newspapers. In the meantime I do not think it will cost me more than 15 cents a lb. f. o. b.

Everyone who visited Jack Tree Hill to see the cotton growing there, including Mr. F. H. Price, the Assistant Government Agent of Kegalla, were agreeably surprised and delighted with the fine appearance of healthy strong bushes heavily laden with crop in all the stages. Mr. Price was much impressed with what he saw, and seemed satisfied that the product would be well-suited for the natives, and took a good deal of trouble to draw up instructions for their guidance, and sent copies to the newspapers. I have seen no cause whatever since, to modify the instructions or reduce the estimate of crop of 135 lb. an acre, and I am more than ever convinced that the product is well suited for natives, and that they will take to it heartily after a time, and that it will find occupation for many thousands of unemployed women and children, and will more than take the place of native coffee of former times. I say more, because cotton will succeed where coffee could not be grown in the lowcountry. For Europeans, cotton will be found a most profitable adjunct in young tea clearings below 2,000 feet, as well as in

cacao or even young coconut gardens. The cotton itself will not take much out of the soil that we cannot spare. The seed will, but it could be returned with the stalks in an improved form.

I have not seen any caterpillars or pests of any kind on my cotton yet, and being well satisfied with the results so far, I have left the bushes for a second crop, instead of putting them out as I intended at first, and they are spreading and seemingly putting on a better crop than the first one.

In sowing or planting out the seed, it must be done at such a time when about three months' fairly dry weather may be expected to ripen the crop from five to six months after planting; occasional showers will not hurt the ripe crop if left to dry on the bushes before plucking.

The cotton your London Commercial Correspondent refers to, as appears in the *Observer* of the 6th, must be mine.—Yours faithfully,

JAS. BLACKETT.

COTTON-GROWING IN CEYLON.

Colombo, 11th June 1889.

DEAR SIR,—With reference to the article in your issue of 10th on cotton cultivation and the prices that the Ceylon Spinning and Weaving Company can afford to pay for cotton, we append copy of a letter that has been addressed to all the Company's agents at Jaffna, Point Pedro, Trincomalee, Batticaloa, Hambantota, Galle, Kandy, Matale, and Ratnapura, from which you will see that we have increased the prices to figures as high as circumstances will admit of, and we feel sure that they will pay cultivators well.—We are, dear sir, yours faithfully, For the Ceylon Spinning and Weaving Co., Ltd.,

DARLEY, BUTLER & Co.,
Agents and Secretaries.

Colombo, 6th June 1889.

"With reference to the arrangements made with you by Mr. W. W. Mitchell regarding the receiving of cotton, and the letter of 20th March to Government, we beg to acquaint you that we have amended the prices which we are prepared to pay for clean cotton, which will be as follows:—

	1st quality.	2nd quality.
Tinnevely ...	25 cts. per lb.	20 cts. per lb.
Kidney ...	30 " "	25 " "
Egyptian ...	30 " "	25 " "
Fiji ...	30 " "	25 " "
New Orleans ...	30 " "	25 " "
Sea Island ...	40 " "	30 " "

The Spinning and Weaving Company regard this as high prices, but they feel prompted to offer them, so that all possible inducement and encouragement may be held out to growers.

"We shall be glad to know if there is any cotton being offered for sale in your district."

THE SETTLEMENT OF CHRISTMAS ISLAND.—The tiny Christmas Island, lying 200 miles south-west from Java, and recently annexed to the British Empire, is to be settled by the Ross family, who for the last half-century have ruled and developed the remote Keeling or Cocos Island in the same neighbourhood. Christmas Island, it will be remembered, is remarkable as being the highest coral island known, and also for the exuberance of its vegetation. The Ross family—the present owner, George Clunies Ross, is son of the original settler—have created quite a happy family in the Keeling Islands, and made them the richest coconut plantation in the world. The people are mostly Malays from the neighbouring mainland, and are all well off and well cared for by their Scottish chief. Mr. Ross sends a ship home every year for the various articles necessary to carry on his life on these beautiful island specks, the only drawback on which is their liability to occasional destructive but infrequent hurricanes. No doubt Mr. Ross will make an equally attractive paradise of Christmas Island.—*Glasgow Herald*.

THE TEA TRADE OF CHINA.

To the Editor of the "*Hongkong Daily Press*."

Sir,—On seeing in your paper the "Report on Tea addressed to the Tsung-li Yamen by Sir Robert Hart" I turned to it with much interest in the hope that so clever a man would have found some means of assisting the China trade in its struggle with India and Ceylon. I was the more disappointed to find that all Sir Robert Hart's ability is devoted to finding reasons and arguments for maintaining the taxes which are slowly but surely destroying China's trade with Great Britain. Many of his arguments are so fallacious that it is surprising to find them advanced as the result of long and patient enquiry.

In paragraph 2 it is stated that "Chinese Tea is superior in flavour to all other teas." This is not a fact, for as regards *choice* teas many gardens in India and Ceylon produce teas fully as good as, if not superior to, the best Chinese product, while if comparison is made between the average quality of the entire crop of India and Ceylon with that of the entire crop of China, all engaged in the tea trade know quite well that the former is immeasurably superior. A very large quantity of the Chinese production is mere rubbish compared with the commonest teas from India and Ceylon, and it is this rubbish which has been one of the curses of the China trade.

Then Sir Robert Hart says that the export of China tea has not fallen off. Even in August, 1888, the date of this "Report," it must have been rather difficult to make this statement. In August, 1889, it will be quite impossible, and by August, 1890, Sir R. Hart will have to bewail a most serious diminution.

In paragraph 3 Sir Robert Hart says that Indian tea can be sold at a profit at about 6d. and from that fact proceeds by a process of reasoning truly Chinese to show that it would be no benefit to the China trade to remit the taxes.

But Indian and Ceylon teas cannot be sold at a profit at 6d. Only favoured gardens can produce teas even at 8d. to 8½d. without loss. But to say that in the struggle which is now going on as to which country can produce the best possible tea at the lowest possible price, China would not be benefited by the remission of a tax which according to Sir R. Hart amounts to 33 per cent. of the cost of the Indian product, is manifestly absurd. To contend for the maintenance of the tax while advocating the paltry remission of the land tax also seems absurd, and that the latter is not collected by the Imperial Maritime Customs seems the only reason for advocating its remission. In paragraph 4 Sir Robert says that "it does not appear to him that deterioration in quality is the cause of less China tea being sold in London." It may not, but to all who like me have been engaged in the China trade for the past 25 years it is most painfully apparent. Look at the melancholy position of Foochow: deterioration in quality has certainly been the cause of decline there; while Hankow teas have borne the strain of competition in that their quality has been better maintained.

In paragraph 4 Sir Robert attempts to account for the badness of London business by the fact that Russia draws her supplies direct instead of taking them through London as formerly. This is not a fact; the badness of London trade is caused by a decreased and constantly decreasing home consumption of China tea and by nothing else. It is true that Russia takes direct what used to pass through London, but by so doing she removes a weight of tea which if added to the present over-supply would only increase the depression.

Paragraph 5 and 6 relate to various improvements in growing, making, and packing teas which the Chinese grower might adopt if his energies were quickened by the remission of taxation. But these improvements will never take place while the trade is crushed beneath the present imposts.

The "Joint commission of intelligent experts," the "Tea School," the "model plantation," the "Tea

MARKET RATES FOR OLD AND NEW PRODUCTS.

COLOMBO, AUGUST 1ST, 1889.

[No. 2.

MR. STREETER ON OUR ISLAND GEMS :

THE PROSPECT BEFORE A CEYLON GEMMING COMPANY.

HE conversation had by our London Correspondent with Mr. Streeter and reported by him in his letter by last mail will have been perused with interest by the many among our readers who have con-

sidered the question of undertaking a local search for gems on a more systematic method than has hitherto been pursued. The rush for shares when the Burma Ruby Mines Company was brought out, evidenced how highly such a form of undertaking is regarded by home capitalists, and it certainly seemed to many of us when that Company was commenced—and does still seem to us—that a soil so rich in its yield of precious stones as is that of certain localities in this island should not be left without a similar endeavour to develop its latent wealth.

We can, however, readily appreciate the distinction drawn by Mr. Streeter between the basis upon which success has been obtained for the Burma Ruby Mines Company so successfully floated under influential auspices, and that upon which Ceylon could, according to his view, at present appeal for similar financial support. It is Mr. Streeter's view, that, until we can place ourselves in a like position with that achieved in Burma, until we can locate the *matrix* which yields our island gems, an appeal to the British public can meet with no satisfactory response. Before considering the several points advanced by Mr. Streeter, it may be of interest to refer to the qualifications of that gentleman to speak with authority on the subject. The son of one of the chief men in the London jewellery trade, he has been trained from boyhood as an expert in the study of precious stones.

We may be assured, therefore, that he is well-qualified to judge of their value and of the position those which are found in Ceylon occupy in the London market in comparison with such as are found in other countries. Mr. Streeter, junior, is well-known in Ceylon (and we have had the pleasure of more than one interview with him), and in Western and Southern Australia as well as in Burma. He devoted considerable time—we believe as much as eight months on the occasion of his first visit to the island—to the examination of our local methods of Gemming, and has therefore had some experience to guide him in forming the opinions he expressed to our London Correspondent. It may first be noticed that that experience leads him to the condemnation of any enterprize which should be undertaken solely in the alluvial soil in which have been deposited the gems now found by local gem-diggers. But, while admitting a certain degree of force in the arguments upon which he bases that condemnation, we would ask:—Have not similar difficulties presented themselves in the case of diamond-mining in South Africa, and have these not been successfully overcome? For we believe it is the case that the great Kimberley mining operations are conducted solely in the alluvial, and that it is in what is termed “blue stuff” that by far the larger proportion of diamonds obtained in South Africa is found. We know that at the place named the diggings are of prodigious depth and extent, and that the alluvial is sufficiently rich in yield to produce large profits. It is an open question, of course, whether the similar deposits of our mountain streams in Sabaragamuwa—especially those of the Ratnapura and Rakwana rivers—have anything like an equivalent depth. This could only be determined by boring, and if examination by such a system was made, it would readily determine the question as to whether we in Ceylon might not profitably follow the example set in South Africa without having to await the chance of a successful result to the course Mr. Streeter recommends, namely, a search for the matrix.

But so far as we are aware no such search for the matrix by anyone thoroughly competent to make it and persistent in following it has as yet been made—at least on the Sabaragamuwa side, although the late Dr. Gyax evidently regarded the Balangoda and Bambarabotuwa country, in which the Kaluganga and its tributaries take their rise, with favour as a rich mineralogical region. When Sir Samuel Baker last visited Ceylon, it was rumoured that he and Mr. LeMesurier of Nawara Ehya spent some time and money in trying to discover the matrix of the ruby on the Uva side of the central dividing range; but without result. The fact however, that, according to Mr. Streeter, in Burma it has now been decided that limestone constitutes the matrix of the ruby, might furnish an indication upon which a search of the kind might well be specially instituted. Indeed we learn that Rakwana proprietors have already given orders to look out for limestone along the sides of the streams cutting through certain estates. It should not require much exploration to expose to examination the veins of limestone in the upper portion of the Ratnapura river, these being doubtless liable to attrition by its waters, and the cost of this work could not be very serious. A question that will be asked is, By whom could such exploration be most profitably conducted? Mr. Streeter recommends the association in this object of the present chief proprietors of gem pits in Ceylon, and we may at least counsel them to consider the matter in their own interests. At any rate the local Gemming Syndicates reported to have agents at work should see to this exploration being accomplished. For, should they not do so, it seems to us far from improbable that our Government—as suggested by our London Correspondent—may be urged to undertake on behalf of public interests a search which would promise, if successful, such large results to the public finances. In such a case, what would become of those private individuals who, it may be, have invested a considerable amount of capital in the industry as at present carried on? It is not likely that, once the Government had established a valuable public property, it would permit, by the granting of further licences, the continuance of indiscriminate, haphazard competition. As has been done in Burma so it would be arranged, we may feel confident, in Ceylon: exclusive mining rights would be leased to the highest bidder, and such an offer we may be sure would come from a public Company formed upon the same lines as has been the Burma Ruby Mining Company. As a measure of self defence, therefore, it might be wise for the persons at present interested in Gemming or in Gem Syndicates in Sabaragamuwa to associate themselves with the view of being first in the field. Many among the native gem-pit owners are known to be possessed of wealth, and the task should, therefore, be well within their means. Mr. Streeter assigns to Ceylon a foremost position among the countries of the world for the richness of its gem-bearing strata. It will be a thousand pities if nothing be done to determine the locality of these and to develop their yield to the fullest possible extent.

We intended to append here a further communication from the writer who has been discussing—at our instance—the case of the Burma Gemming region as compared with that of Ceylon and the encouragement to capitalists to form a Company to work in Sabaragamuwa. This paper must, however, be kept back for another issue. It contains a good many criticisms of Mr. Streeter's statements to our London Correspondent, and altogether we hope the present discussion will go a long way to concentrate

attention in the most likely quarters at home, on the rich Gem region of Ceylon, until practical results by the formation of a strongly supported Company, are achieved.

AN ENGLISH RUBY COMPANY FOR BURMA:—WHY NOT A LONDON GEM COMPANY FOR CEYLON:—NO. IV.

MR. STREETER ON BURMA AND CEYLON:

“CEYLON ONE OF THE RICHEST BEDS OF NATURAL (GEM) WEALTH IN THE WORLD.”

It must not be supposed that when advocating the cause of Ceylon as a prolific field for mining of gems, it is intended to deny the existence in Burma of a profitable field for similar enterprise. Quite the contrary: what is sought to be established is the fact that whatever the case may be in regard to the Ruby Mine Company, the greater advantages and facilities afforded in Ceylon would endow such an industry with far greater certainty of success as a profitable undertaking than would Burma at the present day. At the same time it is but fair and legitimate in this endeavour to divest the former of some of the gilded halo of imaginary wealth with which it has been surrounded. It is interesting to look back at the utterances of Mr. Streeter before the formation of the Ruby Mine Company and compare their tenor with what has been more recently put before the public. “I have,” said Mr. Streeter, “projected many expeditions: some have been successful, others not. It is a great gamble and one must take the good with the bad. In Ceylon I have taken rivers for catseyes and sapphires. Then just before the Burmese war broke out, I was negotiating with Theebaw for a concession to work the famous ruby mines which lie above Mandalay. We have plotted out the road for which we were to receive (paying £20,000 for the mine concession) eight miles on each side of the Irrawaddy, along which the road lies.” By way of interpolation it may be remarked that Mr. Streeter's assertion as to having “taken rivers in Ceylon for catseyes and sapphires” must be regarded as apocryphal; were it a true statement it would have been known in Ceylon long ago. The concession of eight miles on either side the Irrawaddy, it will be observed, is a totally different matter from what has since obtained in the concession from the Indian Government. Considering that the road to the ruby mines now lies over 170 miles up the river, and there are nearly 100 more to the mines; and that the first portion of the distance was covered in King Theebaw's time by steam on the river, it is difficult to know whether Mr. Streeter was again drawing on his imagination, or whether he was under the impression that the valley of the Irrawaddy itself contains precious stones, as a similar locality would do in the gem-bearing districts of Ceylon. Mr. Streeter again writes:—“It is reported that the King of Burma has a ruby of the size of a pigeon's egg, but no European has seen it.” He then alludes to “two most important rubies ever known in Europe,” which did really come from Burma—the poverty of the Burmese Government being the cause of their disposal, as a proof of their being considered something very extraordinary even in the country from which they came,—he adds: “In Burma the sale of these rubies caused extreme excitement, a military guard being considered necessary to escort the persons conveying the package to the vessel.” Under such circumstances we may well believe these gems to have been unique, and as a matter of fact none such have since come to light. Another state-

ment of Mr. Streeter's is well worthy of consideration. "It was thought that when Pegu, the 'Fatherland of Rubies,' was annexed to England in 1852, Europe would be the richer in these beautiful stones, but it has not proved so. It appears that certain dangers exist, or are said to exist, in the lands where rubies are found, such as wild beasts and reptiles. It is possible these may be exaggerated by the ruby merchants in order to hinder competition." Be the reason what it may, the expectation mentioned above has never been realized. Thirty-seven years have passed since the annexation, and we may be certain that in this lengthened period, any exaggerations or fictitious hindrances would long ago have been exposed, and the rubies of Pegu, had they existed in any profusion, would have come to light and been seen on European markets. If this is the truth as regards Pegu, the "Fatherland of Rubies," may it not turn out to be the same as regards Upper Burma?

Bearing directly on this subject, and especially interesting as regards the much talked of jewelry actually found in Mandalay at the occupation by our troops, is a paper by Mr. A. Phillips "On the application of gems to the art of the goldsmith." This paper bears date of 1887, and contains the following paragraph:—"It will be interesting to mark the influence on rubies, once European control shall be definitely established over the Burmese mines. There are those who assert that these mines, scientifically worked, are destined to yield up a vastly-increased quantity of this most precious material. If this were verified, rubies must diminish in value, but on the other hand, a flourishing trade would spring up, as was the case with sapphires when the prolific discoveries in Kashmir reduced by 50 per cent their market value, and admitted their application to jewelry within the reach of moderate incomes. Others assert that the Burmese ruby mines, which have been uninterruptedly worked from early ages, are exhausted with regard to important gems, and that rarely is a stone produced of more than half a carat. My own experience shows this to be an exaggeration. On the interesting occasion of my report to the Indian Government upon the Burmese loot, I found, on the contrary, that a very large proportion of the rubies exceeded half a carat in weight. *Of the quality however, I must say that not one hundredth portion was suitable for faceting or for the European market.* If such may be taken as representative of the Burmese supply, it seems right to conjecture that slight cheapening influence will be brought to bear upon rubies of high quality." Here is indeed a revelation: of all the world-famed wealth of rubies in the possession of the King of Mandalay not one hundredth part was found to be suitable for the London market. This indeed savours a good deal of the rubies of Australia, for a valuation of some thousands of pounds of which a few shillings only were paid in London a few weeks ago. Mr. A. Phillips is the head of the firm "Messrs. Phillips Brothers & Co." founded some fifty-two years ago by his father, Robert Phillips, father and son having alike devoted their lives to the subject-matter of the paper from which these quotations are taken.

There is no need at present to say more about the gems of Burma, but to show what can be proved of the precious stones of Ceylon. In the first instance it may be stated that rubies are not by any means plentiful in the island, they do not constitute the most valuable products of our gem pits. It is to sapphires and catseyes that the greatest importance must be attached, and to a great variety of valuable gems more or less well known on the markets of Europe and America.

As Mr. E. Streeter's name has become a household word in regard to pearls and precious stones, it will be well to quote from his work entitled "Precious Stones and Gems":—"It is acknowledged that India, Brazil and Ceylon have produced larger precious stones and in greater abundance than other lands. Ceylon received yearly a very large sum for its exports, and from this island we even now obtain a large portion of our colored precious stones. During the dynasty of the Kandyan Kings, the right of digging for precious stones was most jealously guarded as a royal prerogative. Under the British Government this monopoly was given up and traders need no special permit." Commenting on the fact that the rare gems are cheaper in Europe than in Colombo he accounts for the anomaly by pointing out that the best and finest specimens are carefully held back by the traders, "who can always ensure a high price for the best Ceylon stones from the native prices of India." This fact, as already pointed out, would be of immense advantage to any Company working in the island. "Rubies are rare in Ceylon, but sapphires common and are remarkable for their colours. Amongst the stones found in Ceylon are corundum, diamond spar in beautiful green crystals, peonaste, asparagus or yellow green chrysolite, cinnamon stone or jaienth, rock crystal, garnets, &c. The yellowish green tourmaline is very like aquamarine, and is found in the riverbeds of Ceylon from whence also comes the brown tourmaline. The value of the tourmaline depends upon the colour, quantity, and size of the specimen. One of exceptional colour and purity, 5 carats weight, would be worth £20. The catseye comes principally from Ceylon and has become more and more fashionable of late years in Europe. There are large specimens at present in the market which are worth upwards of £1,000. Star stones or asteria come from Ceylon. The finest star ruby I have seen was valued at £20; small star sapphires range from £2 to £10, large ones £10 to £100. Zircon, jargon or hyacinth is obtained from Ceylon which is one of the richest beds of natural wealth in the world."

This last assertion, coming from the source it does, is of great value at the present time. Leaving Mr. Streeter's statements, to speak for them selves, the following comes officially from the Assistant Government Agent of Sabaragamuwa, the province most noted for gem-digging.

Discussing the question of the Crown granting leases for gemming purposes, Mr. Saunders about twenty years ago reported thus:—

"It is calculated by those who are qualified to judge of such matters, that if any person bought the right to gem on Crown lands, and could conduct his operations openly, and not as at present by stealth, that he would realise £3,000 a year. The agent here of the principal jeweller (the gem notary) tells me he would be inclined to offer the Government £500 a year for the right to gem in one stream alone—the Niwitigalla river. In 1865 Mr. Birch sold $1\frac{1}{2}$ acre of land in lots and realised £420. One lot of 17 perches or 22 yards square, fetched £117 15s,—and from two pits out of the five which could be sunk on the land, the purchasers realised £300. That stones of very large value are occasionally found is established beyond doubt.

"Idamal Basnaika Nilme found a sapphire in one of his pits which he sold for £300 and it was resold in India for £2,000. He bought another stone for £200 and sold it in Colombo for £365. The gem notary bought a sapphire for £650 from his fellow-shareholders in the Weralupe pits—which is now valued at £2,000 in Ceylon."

In 1881 Mr. Saunders adds:—"The value of gems exported from Ratnapura has increased very much

since 1867. There are large figures, actually realised for stones found almost entirely by sinking little pits usually 10 or 12 feet deep, occasionally as much as 25 feet, and in one instance only, was pumping machinery employed to allow the gemmers to go down to the richer deposits underlying the strata nearer the surface." Again an old colonist with immense experience of the subject writes:—"From time immemorial the island of Ceylon has been noted for its precious stones, and the greatest portion of the island, especially the southern half, is pock-marked with the pits dug by ancient and modern gemmers. With few exceptions, these pits are of the most superficial character, as without adequate appliances it is impossible to keep them clear of water when they are deeper than 15 feet. The Sabaragamuwa district has always been considered the richest field for gemmers, by far the richest has been North Rakwana, which now supplies the chief part of the sapphires, catseyes, and other precious stones sold in Ceylon. The richest fields are situated on a plateau at the base of the Suriyakanda and Kabaragala mountains, on the top and sides of Rakwana, and extending from the Springwood estate on the east, to Martinstown estate on the west. During the last ten years, the gemming by the natives in this locality has been on the most extensive scale, and auction sales of rough gems are not uncommon. It is stated that R90,000 worth of rough gems were sold at one of the auctions, the result of gemming on one of the estates at the foot of the Kabaragala mountain."

It need only be added to this statement, that a considerable area of land is available for purchase in the above-mentioned district; from which selection could be made on behalf of a London and Ceylon Gemming Company.

Mr. A. C. Dixon, no mean authority on such subjects, writes in reference to this part of the country:—"I visited the rich gemming districts of Everton and Batakanda, collecting rough and cut gems as well as their associated minerals. I saw other districts not far away *as yet unworked*, which I have reason to believe will prove richer than the Everton deposit."

Perhaps it may be urged that as sapphires would constitute one of the principal sources of profit to a Gemming Company in Ceylon, any large quantity thrown on the market might cause a serious decline from present value, and on this point the testimony of Mr. A. Phillips is of special value. He says:—"About 1830 sapphires began to rise to exorbitant prices, which were maintained until six or seven years ago, when the large quantities of rough stones brought from Kashmir and Siam literally glutted the market. If the supply be fifty times greater than at the beginning of last century, the demand created by the very cheapening of sapphires is practically certain to stay further decline in value. As an illustration of the plenteousness of sapphires, I recently received, in one consignment, 1,300 stones weighing 4,626 carats, the sterling value of which was £16,680 or an average per carat of £3-12s-1½d." This indeed is evidence of the profit that would accrue on the operations of a Company producing large quantities of sapphires, and the statement that the average per carat value of sapphires is £3-12s-1½d contrasts in an extraordinary degree with the miserable "one farthing each" of the 1,800 carats of rubies which were produced from the Burma mines as mentioned in the last article. Mr. Streeter writes:—"Fine sapphires under the carat in weight, if English cut, vary from £4 to £12; if foreign cut £2 to £5; those of a carat weight £12 to £25. It must be taken as established beyond all doubt that the material

for profitable working exists in great quantity and it remains now to show how it can be made available for the capitalists of Europe. There can be no difficulty whatever in instituting communication between such capitalists and parties in the island, who are both willing and able to acquire the necessary ground for the venture, either by direct purchase, or by lease for a term of years, on annual rent or per acre. Native headmen and holders of temple lands as well as Europeans are alike ready to meet any demand that may be made, and the choice of favorable areas is at the moment probably more extensive than for some time past. In the districts of Rakwana and Morawak Korale, as stated above containing the richest gemming lands in the island, the estates which passed into the hands of Europeans could be purchased at favorable rates. They consist not only of land opened for cultivation of tea and coffee, but with considerable areas of jungle land attached, and these in many instances are more suitably placed as regards gemming than they would be for agriculture—being comparatively flat, wet, localities at the foot of the slope. At one time or other in the long past these were flooded no doubt by the streams from the hills, bearing in the debris brought down by the water, the precious stones which had lain hidden on the mountain sides.

It would probably be considered necessary before deciding on any particular locality for gemming operations to thoroughly prospect it and ascertain from actual experiment what can be obtained from it. Here again the capitalist is met half-way by the landowners in Ceylon, several of whom have already expressed their entire willingness to allow their properties to be prospected, under certain conditions with which there would be no difficulty in complying.

Such a prospecting party could be equipped and complete its work for a sum of £150 to £200, unless of course, it is considered necessary it should be accompanied by an expert sent from Europe. This would naturally be at the option of the capitalists, who would otherwise be able to secure the services of sufficiently competent persons in the island, at comparatively a moderate cost; and perhaps it would be as well if the organisation of such prospecting party were left to the parties in Ceylon who take the matter in hand. But as has been said before, this is at the option of the supporters and promoters of the venture in London, who no doubt would protect their own interests in a practical form. And this protection of their interests as well as the organization of prospecting parties, with the ultimate possession of suitable land for their purpose, would be mere child's play in Ceylon, compared to what it would necessarily be in Upper Burma. That this is really the case needs no further demonstration and would only be a repetition of what has been previously advanced in former articles, and it will indeed be something inexplicable, should such a scheme meet with anything but the most favorable reception by capitalists in Europe who interest themselves in such enterprise.

COFFEE AND GREEN BUG; AND THE KEROSENE EMULSION.

Mr. G. A. Dick of Ragalla, Udapussellawa, expresses the opinion that—"There is no doubt that the kerosene emulsion is a most effective remedy for green bug and that the latter can be driven from field to field and kept in check. I am very hopeful that the bug will soon die out altogether."

COCONUT OIL FROM CUBA.

It has been five years since Cuban coconut oil was offered for sale in this market, and the trade was under the impression that it had retired from commerce for good, but fruit vessels from Cuba have recently discharged at this port nearly one thousand barrels of the oil, which would seem to indicate that its importation was resumed to compete with Ceylon oil. It is stated, however, that the oil was brought here under a misapprehension, and that the low prices prevailing will discourage further importations. Havana may be a better market than the United States at the present time, but its comparative close proximity and the fact that the Cuban industry has been rejuvenated by a Frenchman with a new hydraulic process, will not have a beneficial effect on the local market for coconut oil in the future. The old time rival may continue to seek an outlet here but the success in that direction will depend on quality.—*Oil Reporter, New York, April 24.*

CINCHONA IN JAVA.

The Report of Mr. Van Romunde, Director of the Government Cinchona Enterprise in Java, for the first quarter of 1889, dated Tirtasari, 7th April 1889, is as follows:—

During the months of January and February remarkably little rain fell; but March, on the contrary, was very wet. In consequence of the late setting-in of the west monsoon and the number of dry days in the first months of the year, the new planting could not be carried out as quickly as was desired, and the first plants that were planted out all suffered from the drought at the beginning of the year. However, as exceptionally strong, well-grown seedlings were used for planting, the loss from drying-off is of no consequence. Those that succeeded best were plants that were planted at the end of the quarter. Thanks to the long-continued drought in the year 1888 and the vigorous stirring of the soil carried out during the east monsoon, the plants everywhere grew exceptionally well during this quarter, and the harvestable gardens promise to yield this year a considerable outturn. The upkeep of the plantations during the past quarter required less manual labor than ever before. During the long-continued drought of the past year it was possible to as good as entirely extirpate along-along and other noxious weeds, and in their place almost everywhere has sprung up the *Wollastonia zollingeriana*, which has appeared during the past ten years, and which seldom reaches a height of more than a meter and therefore offers little or no hindrance to the growth of plants of any size. Of all the *Compositae* found in the cinchona plantations the *Wollastonia zollingeriana* is the only one that after stirring of the soil springs up again in the same spot and with the same rapidity and in equal abundance. Only young gardens therefore still require a continuous and careful upkeep. As in the previous year so also during the past quarter the plantations at Nagrak and those on the Malabar mountains and also now again especially the graft gardens at Tirtasari were affected by caterpillars. The insects were caught and killed in thousands. On account of the general good growth however the plantations suffered but little this time from the plague. The last batch of bark of the crop of 1888 was dispatched to Tandjong-Priok about the middle of February. Altogether during the past year 741,799 half-kilograms of bark were gathered. Of this 739,581 half-kilograms were destined for sale in the Netherlands and 2,218 pounds were reserved for the local military medical service. The crop of 1889 amounts to about 175,000 half-kilograms of bark, of which by the end of the quarter 81,479 pounds were dispatched to Tandjong-Priok. For a similar period of 1888 the crop amounted to only 75,000 half-kilograms. Though the much more vigorous growth during this quarter may have contributed very much to the increased crop, the reason therefore is partly to be sought in the fact, that artificial means of drying are now everywhere available. On the 13th of December the last sale of cinchona bark of the crop of

1887 was held at Amsterdam. For pharmaceutical barks of the desired form and of handsome appearance as much as f0.97 per half-kilogram was paid. For ledgeriana and officialis barks the average price amounted to f0.4536 and f0.4655 per half-kilogram. On 17th January 1889 the first sale of cinchona bark of the crop of 1888 took place. In the price of pharmaceutical barks a considerable fall was again noticeable, although quills of handsome appearance still continued to realize high prices. For ledgeriana and officialis barks the average price at this sale was f0.4923 and f0.5376 per half-kilogram. The unit prices—reckoning per half-kilogram bark and per cent of sulphate of quinine—amounted according to reports received at the sales of 17th January, 21st February and 21st March 1889 respectively to 8½, 7¾ and 7¼ cents.

The total number of cinchona plants of all varieties at the end of first quarter of 1889 was 3,328,900, viz., in the nurseries: 1,502,000, consisting of 1,351,000 ledgeriana (including 21,000 grafts), and 151,000 succirubra; and in the open: 1,826,900, consisting of 1,096,000 ledgeriana (including 225,000 grafts and cuttings, and exclusive of the more or less 3,000 original ledgerianas), 5,000 calisaya and hasskarliana, 650,000 succirubra and caloptera, 74,900 officialis, and 1,000 lancifolia (including 250 *C. pitayensis*).

AN OLD CEYLON COFFEE PLANTER AS A VINE GROWER AT SAN FRANCISCO.

The following is taken from the *Aberdeen Weekly Free Press* and refers to an old Ceylon coffee planter:—

The *Fresno Weekly Expositor* of 3rd April gives the following account of the vineyard planted in its vicinity by Mr. W. L. Malcolmson, who is a son of the late Mr. James Malcolmson, Aberdeen:—An *Expositor* representative made a trip to the new Malcolmson vineyard, composed of 160 acres, on Monday, located seven miles due east from this city. The drive is very pleasant from Fresno, passing the Arlington Heights tract on the left and the Windsor Terrace tract on the right, coming out on the Barton Road, and along the south line of the Barton vineyard. Recently there have been several sales of land made in this locality, a tract adjoining the Barton vineyard on the south selling at 50 dollars an acre. Then we came upon the Goodman vineyard of 160 acres, all planted in Muscat raisin grape. Then we pass the Kennedy vineyard, also of 160 acres, which was sold only last month for 75,000 dollars. We now come upon the celebrated Forsyth vineyard of 160 acres, from which the owner netted last year 38,000 dollars in raisin grapes. In and around this vineyard we were shown, and the inviting appearance, the shade, the beautiful miniature lake, the residence, and the broad, level acres, all spoke of comforts which the owner must enjoy. Passing from this vineyard we next drove to the Eggers vineyard, through beautiful avenues shaded with poplars, and everything about denoting prosperity and thrift. Driving due north we then come into the Toll House road, and fronting on this road is the new vineyard, composed of 160 acres, belonging to W. Laing Malcolmson. The soil is of the chocolate sandy loam, of heavy body, in which the raisin grape thrives unusually well. This vineyard is planted in the Muscat raisin grape, and 120 acres of the property are now improved. Mr. Malcolmson purchased the property from Aug. Weihe, of San Francisco, on the 8th of January last. Since then he has ploughed the entire tract, erected a residence, foreman's house, workshops, stables, Chinamen's quarters, corrals, etc. He has also constructed a ditch from the main canal. At present he is making roads, beautifying his residence grounds, and Chinamen are engaged in planting the remainder of his vineyard. Speaking of beautifying his grounds, Mr. Malcolmson has ornamented his front yard in the shape of a shield, the borders and portions of the centre being sowed in blue grass, interspersed with

varieties of rare flowers, which, when all is in growing condition, will render the grounds and house an apparent paradise. There are 15 men employed on the place, ploughing, cultivating, and planting. In his selection of vines he has assorted the Muscat, 70,000 in number, from a stock of 175,000, and getting them in, or a large portion of them, before the rains, they are budding, and it is not expected that one per cent of the vine slips will be lost. He finished the general planting on the 2nd of March, and the advancement made in the short time is wonderful. This year, of course, he expects no returns; next year he will have a moderate crop, and then will follow paying crops from year to year. The vines he set out were rooted Muscat, 12 months old, so that next year he expects to get out of the vineyard as much at least as will pay for the outlay on the grounds. Located as it is, in the midst of the most celebrated vineyards in the State, the soil being so admirably adapted to the raisin grape, Mr. Malcolmson will be soon among the prominent raisin-growers of California. The survey for the new mountain railroad passes on the east and south side of this vineyard, for which he has given permission for right of way. He is surrounded by landowners prominent in the State—H. S. Crocker, of San Francisco, having 80 acres adjoining, Michael Tarpey, and others, who hold their land from 200 dollars to 250 dollars per acre. Mr. Malcolmson is a gentleman who has travelled in various parts of Europe, and at one time was a coffee planter at Ceylon, in the East Indies, where he carried on a successful business for many years. Although coffee-planting may differ from grape-growing, still we predict the same successful management will follow Mr. Malcolmson in his grape-growing enterprise. He has his family living upon the place, Mrs. Malcolmson, a most estimable lady, being deeply interested in the ornamentation of their lawn, and when he has completed his fig and olive avenue from the main road to his residence he will have one of the most inviting spots in the valley.

THE TEA DUTY.

A Liverpool paper says:—"Mr. Picton says that if the duty were abolished 'the consumption of tea of all kinds would be largely extended.' Is this desirable? At the present moment the consumption of tea is over five pounds per head of the entire population. Does it not occur to thinking people that if the people of Great Britain consumed tea at a much larger rate it would hardly be for Great Britain's good? We know that there are those who say that God made the grain and the tea and the devil the whisky and beer. But, if that be so, why do not the disciples of the doctrine eat the tea leaves? And then again, the tea consumed in such abundance is, to a large extent, 'such tea.' Let us say once more that the present duty may be too high; but even apart from revenue considerations, we should be sorry to see no duty at all. When the duty was 1s 9d per lb., tea was, no doubt, much dearer than it needed to be; but it was always genuine good tea. Since the reduction to 6d per lb it is still possible to get pure tea, but so much more difficult that one quails at the thought of the vile stuff which it might pay to import if there were no duty." A great deal of this is rubbish—not the tea, but the writing, and it goes to prove that where Party considerations are concerned all else, even sense, must give way, if necessary. The wisdom of abolishing the duty on tea is a debatable question. Certainly when the Liberals were in office we heard nothing about the proposals for its removal, but the idea that an increased consumption of tea would be prejudicial to the welfare of the country is too silly to call for further comment.

But is there not much to be said in favour of the removal of the tax? Tea has become a necessary of life; and a necessity of life should not be taxed. Secondly, this necessity of life is taxed, and taxed more highly than many of the luxuries of life. It is taxed much more heavily, for instance, than some wines. Tea can be bought in bond for 4½d or 5d. The tax is more

than 100 per cent, on the price of the commodity. If the duty cannot be abolished, it might be diminished. One result of such a step would no doubt be an increase of trade with India and Ceylon, which would be a good thing for all concerned. It would also increase the consumption of a temperance drink. The difficulty is, of course, to find a substitute for the tax, and till that is done, or our expenditure seriously reduced, we cannot sacrifice the four millions and more which it produces. But the duty is almost unique in its kind, as a tax upon a useful food, and Mr. Picton's protest should serve as a reminder to future Chancellors of the Exchequer.—*H. & C. Mail*, May 17th.

GEMMING AND MINING IN CEYLON:

THE OPINIONS OF MR. GEO. ARMITAGE, A COLOMBO EXPERT.

MR. STREETER'S VIEWS CRITICIZED.

Yesterday our representative had the pleasure of a long interview with Mr. Geo. Armitage, the well-known Colombo prospector and mineralogist, on the general subject of mining in Ceylon, and more particularly respecting the views expressed by Mr. Streeter to our London correspondent.

THE ADVANTAGES OF A COMPANY OVER PRIVATE DIGGERS.

Mr. Streeter referred to "the competition of diggers outside of any Association that might be formed." With regard to that Mr. Armitage considered it could not well be prevented in a country like Ceylon where there is much gemming land in private hands. "It would be impossible," he proceeded, "in a free country like this to prevent persons from working, or allowing others to work, on their own land. Where an Association would have the advantage over private workers would be in their working with a large capital and having responsible persons to look after their interests, and also by being able to pass through their mills a large quantity of alluvial, or the matrix containing the gems, against the present laborious, slow and dangerous system—dangerous because it is almost impossible to prevent theft if worked on a large scale. Again, machinery properly adapted for the work would allow of much larger quantities being worked at a time, and also prevent theft. A wealthy Association will always be in a position to keep themselves advised of where good deposits are to be found through their prospectors, and also to purchase, or otherwise acquire, the rights of gemming on land found to be rich in gems. For an Association to derive the full benefit of working out in Ceylon they should have

A CENTRAL FACTORY WHERE STONES ARE CUT BY MACHINERY,

and according to the approved European method. Such a factory there would be no difficulty in establishing in Ceylon, where lapidary work is so much cheaper than at home, and as cutting by machinery would so much lighten the labour of the lapidary, there would be no difficulty in getting the natives to adopt the new system. As it is, if a little trouble be taken with the native lapidaries, they can cut stones almost as well as they are cut at home, notwithstanding the fact that their appliances are rough in the extreme, and the facets of the stones are cut entirely by the eye, the stone being held in the left hand and cut on a vertical lap. With all these disadvantages it is wonderful to see the work they can turn out when trouble is taken with them, and they are made to understand that weight is not the main object to be considered in cutting a stone. Another reason why it is very necessary to establish a factory in Ceylon is to allow of the stones being sent out to the various markets of Europe, Asia, America, and Australia direct, and

without any necessity for re-cutting afterwards. This should insure their selling at from 50 to 100 per cent over what could be expected if they were sent out after the usual Ceylon system, where weight is considered the primary object. The factory should have a branch in Colombo where stones and jewellery could be sold to passengers, and where those who have no idea of the value of gems may feel sure that what they are buying is genuine, and that they are not paying several hundred per cent over its value.

THE PURCHASE OF STONES IN THE ROUGH.

The Association should also lay itself out to purchase stones in the rough from the natives, and thereby minimize as much as possible the disadvantage they may be suffering from the competition of diggers outside of the Association. In this way it would be found that in a short time a powerful Association would soon have almost

A MONOPOLY OF THE CEYLON GEMMING INDUSTRY,

and as a case in point I would call attention to the present Wharf & Warehouse Company, which has a few Boat Companies working against it, but which for all that has more or less a monopoly of the export and import trade of the island.

THE MATRIX OF PRECIOUS STONES.

As regards the matrix of precious stones, the effect of finding the matrix in one part of the island, or for the matter of that in one valley, would not prevent the matrix in an adjoining valley from being worked by an opposition Company, so that I see no advantage in that. In the second place, if we were to find the matrix, and if it were a friable stone, it might be worked without difficulty, or if in a hard limestone it might be worked with acid; but it must be remembered that perhaps several hundred tons of this matrix would have to be worked through to find a really fine stone, though inferior ones might be studded all over it. On the other hand should the matrix prove to be gneiss, such as we find to be so full of garnets in this island, it would be impossible to extract them without injuring the stones. Could we adopt an amalgamating process such as is used in the extraction of gold, it would undoubtedly be a very successful one, but unfortunately we cannot do that. On the other hand in our alluvial deposits of precious stones nature has done for us what we propose doing with the matrix, *i. e.* it has decomposed it and washed away the light and valueless materials and stones, leaving the valuable and heavy ones behind."

MR. ARMITAGE KNOWS WHERE THE MATRIX IS TO BE FOUND.

"But to return to the matrix. If that is all that is wanted, it can be found in Ceylon to my knowledge. I can show it as dolomite and calcite. Where the stones are very thickly studded it might pay, but I do not think it would do so otherwise, unless there happened to be a valuable shoot of a very fine class of stones. Your London correspondent mentions that Mr. Streeter seemed to think that mining operations would safeguard the interests of a Gemming Association because regular mining operations and machinery would be required; but, why should be I do not see, as even the natives are now using machinery in their plumbago pits, and would do so in gemming pits if they had the example set them. Mr. Streeter also advises boring down to considerable depths below the surface. For what reason it is difficult to understand. Our present gemmiferous alluvials have been washed down from higher land where the streams and rivers have been cutting through the gem-bearing rocks, and which

consequently must be exposed, and if covered they can only be so by some few feet of alluvial, for which boring instruments are not wanted. Boring is a most expensive mode of working. It is doubtless economical where you are working, for instance, amongst stratified rocks in search of coal, and where you know that from the upper formation coal is likely to exist below; but to start boring among primitive rocks on the chance of striking on a gemmiferous one seems to me the height of absurdity. If, on the other hand, the limestone crop out as it does in parts of the island, I see no necessity for working very deep to see whether it is gemmiferous unless precious stones are found to exist at the surface, and it is wished to see whether the rock continues to carry them at any depth. Mr. Streeter goes on to say that 'He is certainly of opinion that limestone would probably be found to be the matrix of all or nearly all the gems found in Ceylon.' We may take this opinion for what it is worth, as Mr. Streeter does not give any reason for holding it, and considering the very large alluvial deposits we have, it reads rather like a paradox when taken in conjunction with his remark a little before, *viz.*, 'that he is aware that limestone such as forms the matrix in Burma is found only in limited quantity in the hill country of Ceylon.' Garnets are found in large quantities through our gneiss and schist rocks. The finest crystals of zircon in my collection were found in the disintegrated rock composed of quartz and felspar. Tourmaline is frequently found in quartz, the spinal I have only found amongst limestone. I consider that too little is known to give any opinion as to what rock is likely to prove the matrix of Ceylon gems, and I think it will probably be found that they are not confined to any particular rock."

CEYLON ROCKS ARE NOT STRATIFIED.

"Your London correspondent writes: What a haul it would be for your public finances if a survey conducted by your Government resulted in the finding of the matrix referred to by Mr. Streeter.' He seems to think that all the Ratnapura gems come from one matrix, instead of probably from large numbers. Mr. Streeter seems to have imbued him with his foregone conclusion that limestone formed the matrix, and that they have come from the stratified veins—to use his own expression. Our large deposits of limestone run doubtless in veins, but they are not stratified. Mr. Streeter is very indefinite in his description of the Burma mines. He says: 'In Burma we have discovered the matrix in which rubies are produced, and it is in such a matrix—a kind of limestone—that we are working.' Now, in the first place, I would like to know what Mr. Streeter means by 'a kind of limestone.' Is it a calcite, dolomite, gypsum, anhydrite, wollastonite, or what form of limestone is it? If a calcite, is it crystallised or granular? If the latter, is it a marble or a chalk, or is it simply calcareous marl or clay? Even if he had told us if it were a hard or soft deposit, it would have been something. Then again Mr. Streeter says: 'A stratum of this stone being well defined we have no difficulty in guarding it against poaching.' Does he mean to say that the limestone is a stratified deposit? If so, we have nothing of the kind, as far as I am aware, in Ceylon, but as the corundums are usually associated with the crystalline rocks I cannot but fancy Mr. Streeter has been using a loose way of expressing himself, unless indeed the stratum he speaks of is, in fact, a sedimentary deposit: in which case, of course, however indurated it may have become, it is not the original matrix.

THE MESSRS. STREETER AS AUTHORITIES ON GEMMING
IN CEYLON.

Mr. Streeter's book on "Gems and Precious Stones" is a work that might have been made much of, but is most disappointing to anyone taking a scientific or practical interest in gems. I have not the pleasure of the Messrs. Streeter's acquaintance, and anything I may have said in regard to them has been forced upon me from the prominent position in which your London correspondent and others have placed them as expert, in gem mining. It is quite possible they may be so, but I can only judge from what your correspondent reports.

THE CHANCES OF SUCCESS.

On the other hand there can be little doubt that any company for gemming supported by Mr. Streeter would doubtless stand a very good chance of success from the prominent position held by those gentlemen in the gem trade, but this applies equally to some of the other large firms carrying on similar business.

A GENERAL CEYLON MINING COMPANY.

What is required most in Ceylon is not a Company that would confine itself to gems only, though that would be its chief work, but a general Ceylon Mining Company, with a large capital, and prepared to embark on any profitable mining operations that they may see their way to. And among these gold will doubtless prove one of them. Plumbago mining, scientifically worked, is another valuable industry requiring capital to develop it. The deeper the mines are worked the better the plumbago, and the larger the veins are generally said to be. But this has nothing to do with the special subject you have come to see me about.

HOW SHOULD A COMPANY BEGIN WORKING?

Any Company starting gemming here should begin on the alluvial, tracing it up to its source as opportunities arise. My experience points to the fact that most of our alluvial gravels are to be found within a few feet, generally under 20 ft., of the surface, and they are usually not above a few inches in depth, and rest on the country rock, which sometimes varies considerably, though in close proximity. Careful working is required here, particularly in any land where gemming has not been carried on close by, to ascertain whether the disintegrated rock on which the alluvial gravel is lying is the country rock, or another layer of alluvial soil with a second deposit underlying it of alluvial gravel. And should the pit be small a boulder in what has been the bed of a stream may lead to the erroneous conclusion that the rock bed has been struck. It is, therefore, advisable that a fairly large pit should be made at first, provided the nature of the ground admits of it, and that timber sufficiently large can be obtained in close proximity to support the sides in the event of the ground being swampy."

Such are Mr. Armitage's views, based upon long and practical research in the island. Some other phases of the question might have been enlarged upon, but in the course of this one interview Mr. Armitage has added much valuable information to the important discussion now being carried on. Before leaving Mr. Armitage's office, our representative was shown two or three specimens of Ceylon nuggets from Akuressa, and the bit of coal which Mr. Armitage had just discovered in a sample of plumbago, and which is probably the first coal ever found in Ceylon.

AN INTERVIEW WITH A KIMBERLEY
DIAMOND-DIGGER.

The opinion of a practical man on any question is always valuable, and as so much interest ap-

pears to be taken at the present time in the prospects of the Gemming industry in Ceylon, our representative had a conversation with Mr. Hume Purdie, who is at present dental surgeon in the Colombo Apothecaries' Co., but who some years ago had over 18 months' experience at the Kimberley diamond mines. He thinks the process of mining for gems in Ceylon would be precisely the same as the process of mining for diamonds in South Africa.

"To start with," he said, "the old diamond-diggers used to proceed in just the same way as the natives in Ceylon have worked from time immemorial, but they did not make much until they introduced steam and machinery, and invested capital; then they made their money hand over fist. They found diamonds all along the north of Cape Colony, but the difficulty was to find the matrix. A few diamonds were discovered at the side of a small lake at Kimberley, and then shafts were sunk all round, and in some of them good paying diamondiferous soil was found. Then they passed through several different strata, some of which yielded no diamonds at all, and were, in fact, composed of clay and shale. In digging it was found that the soil for 50 ft. below the surface was purely alluvial. After that they came to the solid blue rock, called among the miners 'the blue,' and when they came to this they thought for a long time that they had come upon useless rock, and the majority of the miners sold out. Those who held on, however, after testing this rock and pulverizing it, found it so extremely rich in diamonds that it was apparent they had come upon the true matrix." This, Mr. Purdie believes, was the first time the diamond matrix was ever discovered. Previously the precious stones had always been sought for in the same haphazard sort of way that they seek for gems in Ceylon. This blue rock, explained Mr. Purdie, showing a specimen, is exceptionally heavy and full of carboniferous material, with garnets appearing at the side and showing innumerable scales of mica. Referring again to the methods adopted by the early diggers in South Africa, Mr. Purdie said that his uncle was one of the Vaal river miners, and afterwards one of the pioneers of Kimberley. When the Kimberley mines were discovered, most of the diggers went there, but some of them to this day continue to work on the Vaal river, earning a precarious livelihood. They come across a good stone sometimes which keeps them for three or four months: just the same as the natives here occasionally come across a valuable gem.

WHERE WILL THE MATRIX BE FOUND?

Speaking about the matrix in Ceylon, Mr. Purdie does not think they will find it on the mountain side as some people seem to think. At Kimberley the mines were discovered on an undulating plain, the real pits being on four little "coppies" or hillocks. Although there is no indication of volcanic action, it appears to some high authorities that at one time the land must have been affected by some similar action, which would have a tendency to locate the diamond-bearing strata. Mr. Purdie's idea is that the matrix will be found on the plateaux. He has come to this conclusion as the result of his South African experience, and the appearance of the mountains here. He has no doubt that if gemmers turned aside some of the rivers, and worked the beds, a good many stones would be found, but they would soon be exhausted, as a true matrix would not be found there. It was proposed to do the same in South Africa before the true matrix was discovered. Mr. Purdie does not pretend to have any special knowledge of the gemming industry in Ceylon, but it is his opinion

that it must be conducted in exactly the same manner as the diamond diggings, and he does not believe the industry here will pay till the true matrix is found. Then how is the matrix to be found? He thinks that there are sure to be good paying pits at present in its neighbourhood, but the owners have not gone down far enough through the different strata to reach the true deposit. To the expert there will doubtless be special features of the country which will indicate the existence of the deposit underneath. The strata that he has had experience of have always been very hard rocks, and he thinks the strata here will be the same, and that they can be pulverized by the action of water and the atmosphere.

HOW TO GET THE GEMS FROM THE STRATUM.

In South Africa they blast out the stratum in great blocks, and then break it up with picks. They then expose it to the atmosphere and the rain, by spreading the blocks on the veldt for four or six months. The pulverized rock is then put through the washing machines at the rate of 300 or 400 tons per day. It is the quantity that they can get through that makes the mines so valuable. The veldt is not enclosed, but radiates from the mines, which are in the centre, to a distance of three or four miles.

To return to Ceylon, Mr. Purdie has an idea that the matrix at one time extended almost to the surface, but that the action of the wind, the atmosphere, water, and decayed vegetation has formed a very deep alluvial soil, which must be got through before the matrix is exposed. It will be necessary in prospecting to sink shafts to a considerable depth. He thinks the matrix will be composed of carboniferous material, the same as the diamond matrix, which will include sapphires, rubies, catseyes, etc. As all have been formed by the same action, they will all be found together. When the true matrix has once been found, he thinks the industry might prove remunerative to British capitalists.

A SABARAGAMUWA MAN ON MR. STREETER'S CONDEMNATION OF CEYLON.

A Ratnapura correspondent, well-up in the subject of gemming, writes:—

"I admire your Burma and English ruby mining correspondent in his letter No. 4, in his justifiable and deserving criticism of Mr. Streeter's condemnation of Ceylon as a suitable field for the operations of a Gem Mining Company. Why, according to Mr. Streeter's own admission, Ceylon produces about one-third of the whole of the world's gems. What an absurd idea that without finding the matrix: no Company would be successful! What are the several strata one deeper than the other, of gem-yielding gravel, but the matrix, at least the only one known to exist in Ceylon, and it is from them, and no other source, that the river gems are washed down the streams, and found—some worn round and some in crystal, according to the distance travelled. The gem stratum or illan is to be found nearly all over Sabaragamuwa, from the very surface to an unknown depth. In fact I have seen places where the whole hillside is illan, and it has been turned over like a road cutting and washed and carefully searched to a depth of 30 to 40 feet, making thousands of pounds of profit for the lessee."

ANOTHER BIG ALEXANDRITE.

Seyid Ahamadu Moulana is a lucky man. Not long ago we were told that he had found an alexandrite weighing 26 rupees, on his land at Weligama, and that this precious stone was sold for R14,500. Now it is said that he has become the possessor of another alexandrite weighing 6 lb, and

8 rupees which has been found at the same place. Some say it is valued at R200,000 and others at R150,000. There is, however, we hear, a dispute about the ownership of the land.

Our Galle correspondent writes:—

GALLE, 10th June.—From Weligama comes the news that another alexandrite has just been discovered by the Moorish priest (mowlana) weighing 6 lb. and 8 rupees. It is stated that the gem is fully worth R200,000. If so this monster stone must be considered as one of the most remarkable finds ever made in Ceylon. It is a curious coincidence that nearly all the valuable alexandrites found in the island should have been discovered in the gem-pits owned by this priest.

PURE ARROWROOT FLOUR.

Mr. R. P. Jayawardana of Kotte, who is the Head Clerk of the Provincial Registrar, Western Province, has been favoured with a certificate from the Chairman, Agri-Horticultural Show, Kandy, held on the 24th and 25th ultimo, to say that he has won a silver medal for his arrowroot known as "Jayawardhanapura" arrowroot. Mr. J. has had reason to suspect the purity of the stuff sold in the native market as "arrowroot," and had been induced to attempt to produce a really pure supply of an article that is so largely recommended by medical men. The arrowroot of the native market is largely adulterated with the starch of the sweet potato, the cassava and rice,—an article which the doctors recommending "arrowroot" would hesitate to permit their patients to take. The lowness of the price, viz. 12 to 20 cents the pound, is sufficient evidence of the inferiority of the stuff; a pound packet of "Jayawardhanapura" arrowroot is 35 cents, a half-pound packet is 18 cents. Mr. J. is taking a great interest in inducing the villagers of Kotte and its neighbourhood to go in largely for arrowroot cultivation, and they have taken to the work rather readily. Mr. J. himself has planted over 12 acres of ground with arrowroot, and he is steadily extending his cultivation and preparation of the flour, which is being done in a small hand-mill, turned by two blind paupers, who were, a year ago, begging about from door to door to the annoyance of many. Mr. J. also supplies employment for some women, children and men in Kotte at his arrowroot establishment, and he appears to be very proud of the medal he has won, because he values it better than an honorary rank nowadays conferred by the Government, for a medal of the kind is an admitted guarantee of the industry and perseverance of its recipient. Mr. J. has had a silver medal awarded in 1888 by the Chairman of the A.-H. Show at Nuwara Eliya.—Com.

AN ENGLISH RUBY COMPANY FOR BURMA:—WHY NOT A LONDON GEM COMPANY FOR CEYLON?—NO. V.

MR. STREETER ON BURMA AND CEYLON:

"CEYLON ONE OF THE RICHEST BEDS OF NATURAL (GEM) WEALTH IN THE WORLD."

CRITICISMS ON MR. STREETER'S OBJECTIONS TO A GEMMING COMPANY FOR CEYLON—THE LATEST FINDS OF ALEXANDRITES—AUTHORITIES ON MINERAL WEALTH OF CEYLON: DR. GYGAX AND MR. A. C. DIXON—GEM-PRODUCING MATRIX AND CENTRES OF CEYLON—DEMAND AND SALE FOR PRECIOUS STONES.

A report of Mr. Streeter's conversation with the London correspondent of the *Ceylon Observer* having just reached the island, a few remarks upon that gentleman's objections to a Gemming Company for Ceylon will appropriately follow what has been written previously.

He says:—"In the first place the main obstacle must be the competition of diggers outside any association that might be formed. Ceylon is not at present circumstanced as we are in Burma

where the whole range of the mining country is within our concession, within which we can readily put a stop to any illicit proceedings. Unless something could be done to put a stop to the competition named, I do not see how any company could work successfully." In reply to this it may be once for all stated that it is no part of this contention to seek for a monopoly, or to hinder other parties or companies from doing all they can in similar enterprise. The deposits of gems have been proved sufficiently extensive and sufficiently valuable to supply all comers, and all that a London company would require is a few acres of the best land obtainable. They could safely allow others to work where they pleased. Of course, it would make assurance doubly sure were the company to secure lots of land in different districts, say Ratnapura, Rakwana, and Morawak Korale, and this could be done without any difficulty whatever. As for the Ruby Mine Company having secured in their concession the whole range of mining country in Burma, it is simply untrue, as has been demonstrated in former articles, and if Mr. Streeter really entertains any such impression, his projected journey to Burma will most assuredly disabuse his mind of anything of the kind. He will then find out—if he is not already aware of the fact—that the opposition he so triumphantly asserts cannot possibly exist has already begun to make itself distinctly manifest. He will find that "application has been made to the local authorities at Mandalay for a concession to work mines containing precious stones by parties whose pecuniary and commercial status is unexceptionable," and that the Chief Commissioner has not replied "The concession to Mr. Streeter debars me from granting your request," as no doubt he would have done, were such the case. No, the matter has been referred to the Indian Government in the usual formal way, and a reply will be forwarded in due time. Nor does it occur to the local press that any such hindrance exists; for whilst commenting on the incident, the Mandalay paper, without any reference to the Ruby Mine Company's so-called monopoly, criticizes what it terms the "technical obstruction" shown in the course of procedure and passes some rather severe strictures on the system by which the Chief Commissioner is compelled to refer so trivial a matter to the Government of India, and thereby throwing impediments in the way of the development of the country. Now it happens that the editor of that journal is intimately acquainted with every phase of the ruby question, and the working of the Ruby Act in Burma, as well as the constitution and standing of the Ruby Mine Company, and had there been an impression in his own mind, or amongst the public of Mandalay, that Streeter's concession stood in the way of the application under reference, or any other concession of the kind, we may be sure he would not have hesitated in making it known and referring to it at length in his article. Nothing is known at Mandalay of any such monopoly as is claimed by Mr. Streeter, and such being the case is in itself very strong evidence that it does not exist.

Mr. Streeter objects that whereas in Burma they have discovered and obtained possession of the "matrix" which produces rubies, in Ceylon all the precious stones have as yet been found in the alluvial; until the matrix has been discovered in Ceylon, a Company would not pay. In regard to Burma, the Ruby Company have discovered and secured just a little minute portion of the matrix, if they have found it at all, and it may possibly prove to be very prolific and profitable as far as it goes; no reasonable person can surely

wish it otherwise. Mr. Aubrey L. Patton, who in a letter to the *Pioneer* says he alone is responsible for the amount of the tender for the lease of these mines, points out very fairly that the whole capital of the Company, £300,000, may be realized in a few lucky finds. The same can be said of a Company working in Ceylon, where a capital of one-twentieth part of that of the Burma Company would suffice. But we contend that in Ceylon there is no occasion to trouble ourselves about the matrix when the alluvial deposits have been proved to supply all the elements necessary for profitable mining. The latest find of importance is thus announced in a local print:—"There not long ago appeared in the papers a story of an alexandrite which had been found by Seyid Aheer on his land in the Morawak Korale, weighing twenty-six rupees' weight, and which was sold for R14,500. We now hear that the same proprietor has found another 6 lb. and 8 rupees in weight, which is valued at R200,000!" This beats the record of lucky finds. Alexandrite was lately valued at £2 10s per carat. If considered of advantage by all means search for the matrix, which is by no means so unknown as Mr. Streeter would have us believe. That rubies and garnets of very small size are found in limestone in Ceylon is beyond doubt—the Ramboda limestone is studded with them, but there is no record of anything of marketable size having been found. Then Mr. Dixon tells us that the same thing occurs at Wilson's Bungalow; and the dolomite at Wariapola in Matale contains a large quantity of blue spinel. As regards sapphires (which embrace rubies), Mr. Streeter has told us "precious stones and gems are found most frequently in secondary deposits, loose in sand, or in débris with other precious stones. Occasionally, however, it is found embedded in primary deposits, in granite, syenite, basalt, gneiss, talc and hornblende, strata of spicular iron, and magnetic ironstone." Bearing this in mind, especially as regards gneiss, it will be seen that Dr. Rudolf Gyax in his report made to Lord Torrington as far back as 1847-48, fifty years ago, had then hit upon the matrix from which the ruby is produced. He says:—"I found at Hima Pohura on the south-eastern decline of the Pettigalakanda, about the middle of the descent, a stratum of grey granite containing, with iron pyrites and molybdena innumerable rubies from one-tenth to one quarter of an inch in diameter, and of a fine rose colour, but split and falling to powder. It is not an isolated bed of minerals, but a regular stratum extending probably to the same depth and distance as the other granite formations. I followed it as far as was practicable for close examination, but everywhere in the lower part of the valley I found it so decomposed that the hammer sunk into the rock, and even bamboos were growing on it. On the higher ground near some small round hills which intercept it, I found the rubies changed into brown corundum. Upon the hills themselves the trace was lost, and instead of a stratum, there was merely a wild chaos of blocks of yellow granite. I carefully examined all the minerals that this stratum contains: felspar, mica and quartz, molybdena and iron pyrites, and I found all similar to those I had previously got adhering to rough rubies offered for sale at Colombo. I firmly believe that in such strata the rubies of Ceylon are originally found, and that those in the white and blue clay at Balangoda and Ratnapura are but secondary deposits; I am further inclined to believe that these extend over the whole island, though often intercepted and changed in their direction by the rising of the yellow granite." Dr. Gyax adds that having often received the minerals of this stratum with the crystals perfect, he had

reason to believe that places were known to the natives where such mines might be opened with confidence of success. Sir Emerson Tennent commenting upon this report says:—"It is highly probable that the finest rubies are to be found in these strata, perfect and unchanged by decomposition, and that they are to be obtained by opening a regular mine in the rock, like the ruby mine of Badakshan in Bactria, described by Sir Alexander Burnes. Rubies both crystalline and amorphous are also found in a particular stratum of dolomite at Bulattota (Rakwana) and Badulla, in which there is a peculiar copper colored mica with metallic lustre. It is strange that although the sapphire is found in all this region in greater quantity than the ruby, it has never yet been discovered in the original matrix, and the small fragments which sometimes occur in dolomite show that there it is but a deposit."

From such evidence as we here possess, it may be deduced that gneiss forms the gem-bearing matrix of Ceylon—gneiss of which the whole mountain region of Ceylon is composed,—and as further proof of this, rubies and other gems are found at Nuwara Eliya over 7,000 feet above sea-level, in Dikoya and the Bogawantalawa patanas at near 6,000 feet. In fact the matrix is the whole of the hill country of Ceylon, the higher portions of which have ages ago become decomposed and the precious minerals have become scattered and washed down the mountain torrents on all sides. Mr. Streeter talks of the source of the Ratnapura river as a locality comparatively easy of exploration, and as if the lower bed of that river were the principal field for gemming in the Sabaragamuwa district. The sources of the rivers which form the Kaluganga are innumerable, each stream having its own source and own gemming localities along its course. Some of the streams rise in Rakwana, some in Bambarabotuwa and all along the Adam's Peak range. Each of these may be said to have its own matrix for the gems it produces, if it still exist. Again, suppose the gems are found imbedded in the gneiss, they could not possibly be extracted without enormous expenditure by blasting. The gneiss of Ceylon is as hard as granite and as difficult to move from its bed. However, there is no insuperable difficulty preventing the search for the matrix suggested by Mr. Streeter, should it be considered necessary.

Again Mr. Streeter characterises as an objection, that stones found in Ceylon realize as much locally as can be obtained for them in the European markets. Mr. Streeter here looks at the matter from a jeweller's point of view, he would no doubt prefer all the gems to be sent to him for sale, and for his benefit in the way of commission on the transaction; but it must be very obvious that the shareholders of the Company would look to the return on their venture, it would be immaterial to them whether their dividends were realized in Ceylon, or at home, as long as they made the most they could out of their capital. At the present moment considerable quantities of sapphires are sent from Ceylon to Australia and America—and a local demand arises which would be in favour of the miners. In Burma Mr. Streeter has to buy a large proportion of the rubies sent to Europe for the Company, and local competition is consequently dead against the interests of that Company; in Ceylon it would be the exact reverse. Another objection now put forward is that the reduction in size, necessitated by the grading in colour, reduces the value of sapphires. In his "Precious Stones and Gems" after commenting on the value per carat of sapphires, he says: "Sapphires, do not, like rubies, rise in

price as they increase in size." In opposition to his latest assertion that "catseyes are not favourites with purchasers of jewellery generally," he says in the same work. "The catseye has become more and more fashionable of late years in Europe and its value has greatly increased," and in India it has always been much prized, and is held in peculiar veneration as a charm against witchcraft. Mr. Streeter's opposition to a Ceylon Gemming Company is easily explained: having floated the Ruby Mining Company for Burma, he no doubt finds it as much as he can at present undertake to keep it going, and he naturally would view with alarm any undertaking in Ceylon in which he did not play a principal part. Again Mr. Streeter is perfectly aware that a Ceylon Company would realize its produce in the best available market, and that market would possibly not be in London where the jewellers would have the pickings of the sales, and this also militates against his interests in business.

INSECT ENEMIES.

A MECHANICAL MURDERER.

Not far from a tree on her Majesty's home farm at Windsor which marks the spot where the late Prince Consort finished his last shooting, an interesting agricultural demonstration was witnessed on Saturday. The enormous depredations caused by insects is one of the difficulties with which agriculturists have to contend, and for years they have been seeking for some effective means of destroying these pests and preventing their ravages. Mr. G. F. Strawson, of Newbury, Berks, has invented a machine for this purpose, which he has named the pneumatic distributor, and two of these were shown at work at Windsor. The liquid or solid which is to be distributed is placed in a tank or hopper and a fan which is driven at a great speed by the revolutions of the wheels of the machine scatters it over the plants or land to be covered. Thus paraffin falls in a fine spray, and powdered lime is emitted in a white cloud like smoke, covering everything over which they pass with a fine film or coat, sufficient to destroy the dreaded fly. A horse travelling quickly with one of these machines can travel over a ten-acre field in an hour, so that rapidity, which is so essential when a crop is attacked, is secured. The smallness of the quantity of material used is surprising, a pint of paraffin being sufficient to cover an acre, and yet so effectively distributed is it that a single leaf cannot be picked up without the smell of the liquid being detected. As well as for ground crops, the pneumatic distributor is adapted for hop fields, vineyards, and orchards, special shapes being made to suit the form of cultivation. But the uses of the machine by no means end here. Its power of distributing is also available for fertilizers, and nitrate of soda, for instance, which must be handled very carefully, can be laid down with perfect evenness and in regulated quantities. As a broad-cast corn and seed sower it also does work of a perfectly even and accurate character. So far as an agricultural implement; but it has, further, its town uses. In the distribution of disinfectants either in a liquid or powdered form it has obvious advantages, and its use for the distribution of sand on asphalt and other slippery roads would undoubtedly prevent many accidents from the falling of horses. The machine can be worked either by horses or hand power, and by one man. The French Minister of Agriculture is very sanguine that the "Strawsonizer," as it has been named, will out the dreaded phylloxera from the vineyards of France.—*Pall Mall Budget*, May 24th.

IMPROVED PADDY (RICE) CULTIVATION.

Office of the Director of P. I.,
Colombo, 15th June 1889.

To the Editor of the "Tropical Agriculturist."

SIR,—I am directed to forward for publication the enclosed copy of a communication from the Govern-

ment Agent of the Eastern Province on the subject of improved paddy cultivation.—I am, sir, your obedient servant,
H. W. GREEN, Director.

COPY OF MR. ELLIOTT'S LETTER REFERRED TO.

Batticaloa Kachcheri, 24th May 1889.

The Director of Public Instruction, Colombo.

Sir,—I have the honour to invite attention to the results of the two experimental cultivations of paddy with *hired labor* carried out by two of the Instructors furnished by you, one working on land near Galle and the other at Nindoor in the Batticaloa district. Neither of these men knew what the other was doing, and it is only the accident of my recent removal to Batticaloa which has brought the second case under my notice. I attach importance to the experiments as they were both conducted *with labor* paid for in money and hired at ordinary market rates. The results, therefore, may be accepted as answering, and that satisfactorily, the question "Does paddy pay?" and may prevent the resurrection of the cry that it *does not* which I believe my paper on rice cultivation published in 1883 went far to refute. At that time I could only give the results of careful inquiries and the deductions made, but the data now obtained are of a far more exact nature and should consequently be more convincing.

2. In both cases the fields cultivated were ordinary village lands, similar to hundreds of acres in the neighbourhood; the Batticaloa field had had the advantage of being irrigable from one of the large works, but the Galle land was dependent on rain and the water of a fair stream. The crop was reported to have been damaged by flies and an excess of water at the beginning of the season. No manure was used at Batticaloa but a little used at Galle, as it was customary to do so in the tract, a very old one, usually cultivated twice in the year. In both instances the lands were ploughed with the improved ploughs introduced by you and allowed to lie fallow for six weeks, when they were cross-ploughed with the native plough. In Batticaloa the landowners are much impressed with the deep ploughing, and I have many applications for ploughs and there seems every likelihood of their general adoption. In each case a portion of the land was sown broadcast in the native manner with the quantity of seed usual in the district. The rest of each land was planted with seedlings raised in a special bed, leading to a great saving in the cost of seed, though entailing additional labor in transplanting.

3. I annex a very full statement showing the cost of each detail in the process of cultivation, which may be summarized as follows:—

	Galle	Trans-planting	Broad-cast	Total
Area cultivated in acres	1			2
Quantity of paddy used as seed in Bushels	3	2		
Area cultivated in acres	3	4		7
Quantity of paddy used as seed in Bushels	3	12		
Galle:				
Cost of seed paddy	R 00'60	3'00		3'60
Expenses of cultivation	14'94	13'28		28'22
Total Cost	15'54	16'28		31'82
Batticaloa:				
Cost of seed paddy	1'00	10'00		17'00
Expenses of cultivation	30'35	44'11		74'46
Total Cost	31'35	60'11		91'46
Galle:				
Total crop in Bushels	36	28½		64½
Cost per bushel	cents. 43	57		49
Batticaloa:				
Total crop in Bushels	118½	189½		3'7¾
Cost per bushel	cents. 26	31		29½
Galle.				
Batticaloa.				
Gross value of crop	R. 66	308		
Deduct Grain Tax	2½	14		
Net profit say	64	294		

Selling value of land	180	420
Percentage on capital invested	40	70

Labor is dearer in Galle than in Batticaloa: hence the higher outlay in the Southern Province where some of the men were paid as much as 32 cents a day.

4. The important point which these experiments establish is that with the moderate crop of 32 bushels an acre in an ordinary unirrigated land, it is possible in the Southern Province to grow paddy at 50 cents a bushel or 55 cents including payment of the Government dues. In Batticaloa the cost is still lower viz., 29½ cents or 35 cents including the Government dues, and if a proper system of transplanting be followed the cost can be reduced to 26 cents a bushel. These results fully bear out the conclusions arrived at in my paper on rice cultivation.

5. It is interesting to note that in both cases, where the transplanting system was followed, there was such a saving in the cost of seed paddy as to much more than cover the additional outlay on the necessary labour and that the system led to a saving of 16 to 25 per cent on the cost per bushel.

6. To anticipate the objection that may be taken that these results are secured by an improved method of cultivation and so do not affect the position of the ordinary cultivator, I would point out that this higher tillage is far more costly, probably double the outlay that an ordinary native proprietor would incur. Indeed the Vanniya of Sambanturai who has cultivated some of his land with hired labour informs me it cost him R7'50 an acre (sowing broadcast). The crop of the Batticaloa land experimented on is ordinarily about 135 bushels, which would give 35 cents a bushel as the cost on an expenditure of R7'50 an acre. The poorer cultivator who from a variety of causes limits his expenditure in money or labour on his land I believe secures a crop in proportion to his outlay. This is the real secret why the native cultivator adheres to paddy cultivation and is satisfied with his gains, though his English critic cannot understand the position and hastily concludes paddy cannot possibly pay or is "notoriously unremunerative." In other branches of industrial occupation it is the same, *i.e.* out of citronella, coir, cinnamon, the native makes a profitable return on rates which the European cannot touch.

7. I take this opportunity of acknowledging the very important work the instructors sent out by you are doing, in placing before the people of the various parts of the island improved methods of cultivation and establishing the possibility of carrying them out remuneratively. I would urge however the instructors' efforts be not hampered by making them dependent for labour on schoolboys or other such unreliable sources. I think they ought to be supplied with funds to hire all labour required. Confident of the result in Galle I advanced the funds, but in Batticaloa the instructor finds his own money and in return takes the entire crop, less what he pays as rent. In most Kachcheries there are generally funds, such as irrigation fines, &c., which might be legitimately advanced for the purpose at first and the profits would very soon accumulate to a sufficient figure to cover subsequent outlay. The instructor should be given a percentage of the profits to stimulate his efforts, but there is no necessity to give him the entire produce. As some Agents may object to advancing funds, it would be well to obtain the formal sanction of Government to the system.

8. I have such confidence in the results and the beneficial effect that I purpose, during the next harvest, undertaking cultivation in five or six different localities so as to bring the method followed more widely under the notice of the native cultivators in all parts of the district, as well as to offer the gratuitous supervision and advice of the Instructors and the loan of the improved ploughs to any proprietor who may desire to avail himself of this assistance. I have already asked for a dozen ploughs and I should be glad to know on what terms I could secure the services of two more instructors, who might be quite

junior men who have recently left the Agricultural School, as their work would be under the general supervision of Mr. Chelliah.

9. In view of the important results secured, I would suggest you should communicate this letter to Government and obtain permission for its being communicated to the newspapers in hopes it may allay the cry of paddy not paying, which has of late been revived.—I am, &c., (Signed) E. ELLIOTT, Govt. Agent.

SOMETHING ABOUT TOBACCO.

A planter of wide experience in the island writes to us as follows:—

It has always been strange to me that European capital was never invested in tobacco in Ceylon. The plant has been cultivated by the natives from time immemorial. Whether the *Mahawanso* has any mention of it I do not know, but long before the English came here tobacco was grown in various parts of the island, and is so still. It is not necessary to refer to the large area in Jaffna cultivated with the leaf, but, if anyone journeys through Uva, in the villages in the Badulla district, and throughout Udakinde, little plots of tobacco and in some cases solitary plants placed along the lower sides of drains cut in a cabbage garden, are invariably to be seen. I have even met with it as high up as Wilson's Bunglow and the villages below Haputale, whilst lower down by Dikwella and on towards Passera the plant grows very luxuriantly. When I first came to Ceylon in the sixties, and for some time afterwards, we used to smoke nothing else but Uva cigars made and grown in Uva, and very good they were too. Now I think all the tobacco grown there is used by the natives. It grows freely to my knowledge throughout the Jaffna peninsula, the Eastern Province, and in a part of the Southern, and in the greater part of the North-Central Provinces. Any attempt to grow it in the Western Province will end in failure, in my opinion. As for the Kanthalai scheme of the Ceylon Tobacco Company, they will have to be very careful of floods in the rainy season. When I was last there the country around was all under water. It was early in December four years ago. But it will grow splendidly over a large area of the island. All that is wanted is an experienced Dutch planter to teach us how to cure it. To obtain the services of a reliable, trust-

worthy, and experienced tobacco planter would cost a lot of money. He would require high pay, and it will be difficult to get just the man wanted. Far better send down a smart man from this to learn the work.—Local "Times."

TOBACCO CULTIVATION IN TRINCOMALEE.

Traders from Jaffna have come here with orders from their respective firms to buy tobacco, and my modest estimate of the money that will flow into Trincomalee by this source is R50,000. It is evident from the rush of these men that there is keen competition among them—so much the better for the local tobacco-growers. A fortnight more will have to pass before the leaves attain the stage required to make them marketable; but, notwithstanding this fact, advances have been made and cultivators are having a good time of it.

While on this subject I will describe for the information of such of your readers as are interested in tobacco cultivation the mode or process adopted in this country for growing and curing it. In the month of September the seeds are sown in an enclosed nursery and watered daily till November, when they are removed and planted on the land selected for the purpose, at a distance of about 1½ cubits from each other. The soil, of course, must have been well manured with cow-dung for at least a month, and ploughed well once or twice, before the planting commences. As the seedlings are deposited in their places, shady branches of jungle trees are also deposited a few inches from the plant, the leaves of which serve to keep off the sun from the tender plants placed under their protection. Water is poured over the plants rather sparingly every morning and every evening for a fortnight, and as they take life and grow the now already dried-up withered jungle branches are pulled out and the soil round about the plants is dug and loosened, rendering the shooting of the roots easier. After fifteen days the plant is watered profusely once a day. Another fortnight or twenty days more the soil undergoes hoeing again, which is done with the greatest care so that the young plant is not injured. On the day of hoeing, as well as the following day, no watering takes place, the plants being left to droop a little. After hoeing, the ground is divided into small beds, having four plants standing, one at each of the four corners of the beds; while the water is let inside the bed from the third day, as usual once a day. About twenty or twenty-five days after, the crown or the bud of the plant is nipped off. The leaves that hitherto were wanting in sap for their growth by reason of the greater part of it being carried up to the top by the main channel of the stump or trunk, now receive the bulk of it, and luxuriantly thrive. Once in every week the trees are inspected, and the branches broken off. Rain is wanted at intervals of a fortnight, particularly during January, February, and March. Thus nursed, at the sixth month after its planting the tree is cut down entirely and hung downward in a shed through which the breeze plays freely, but the sun is not allowed to enter. Left here for twelve or fifteen days, the verdure of the leaves changes into a brown color, when the trees are taken down and piled one over the other and covered with dry plantain leaves, where they lie for another twelve days. On the thirteenth day the leaves are separated from the trunk, sorted into three kinds or *thamsu* (the best, the second rate, and the refuse) made into bundles of twenty leaves each, and piled again in the same way as before. This is the crowing operation, letting the leaves remain there for ten or twelve days. The trader then comes and buys them at prices ranging from R10 to R18 a thulam, a *thulam* being twenty-four bundles of twenty leaves each. The process of curing tobacco in this country differs widely from the method followed in Jaffna, where smoke has much to do in the process of curing. Smoke is never utilized for Trincomalee tobacco. I herewith send a parcel containing two leaves of tobacco as sample mostly cultivated here, and eagerly sought after by the Jaffna traders.—Cor. Local "Times."

THE PAMPAS PLUME INDUSTRY.

The Pampas Grass (*Gynerium argenteum*) is a native of the Pampas plains of South America, and was introduced into the United States about 1848. It is not sufficiently hardy to stand the rigour of Northern winters, but is in the cold parts of this country [United States] frequently planted on the lawn in summer, and upon the approach of cold weather is transplanted into a tub, and carried into the cellar. In California it is perfectly hardy, and a hill will sometimes attain a height of 20 feet, a diameter as great, and a weight of 2,000 pounds. There would be quite inconvenient for our Northern friends to handle in the cellar. The plants are easily produced from seed, but as the sex and variety are very uncertain, they are usually multiplied by dividing the female plants, the plumes of which are much more beautiful than those of the male.

For many years the Pampas Grass was grown only for ornament, but in 1874 the difference in sex was discovered, and since that time the industry has gradually increased.

In 1872 I planted seed; in two years several hundred of the plants produced plumes. Many of these were sold when small plants to persons purchasing them purely for ornamental purposes, but the variations in shades and fineness were very marked.

In 1874 the discovery was made that by pulling the immature plumes from the sheaths, and exposing them to the hot sun, the male plumes would hang heavily, like Oats, while the female would fluff up and become light and airy.

We saved a quantity of the female plumes, some of which were sold in Santa Barbara, while others were sent to San Francisco in November, 1874. Samples were also sent to Peter Henderson & Co., of New York. Three hundred were ordered at once, and the following day instructions were received to double the order and send by express. This was the first lot of good plumes ever sent East from California, and was the beginning of the present Pampas industry.

My plantation has been extended to 5,000 hills, and there are a number of other quite extensive plantings in the neighbourhood of Santa Barbara. The plumes shipped from Santa Barbara have the reputation of being, and are undoubtedly, the finest sent to market. The crop this year is estimated at 1,000,000 plumes. The demand for the last two years has been good, but the prices have never been so high as they were at the beginning of the industry—200 dols. per 1,000 plumes. The decrease in price was gradual until 1886, when sales were slow at 30 dols. per 1,000. Some of the growers did not harvest their crops that year, and destroyed their plants. In the fall of 1887 plumes were in demand at 40 dols. per 1,000 and in 1888 they were scarce at 50 dols. and 60 dols. per 1,000 so this winter there will be a large increase in acreage.

Pampas Grass plants should be put on the best valley land, at a distance of 10 by 16 feet apart. Some are planted closer, 8 by 10, and 10 by 10 feet; but if they are to be allowed to become old plants, it is better to give plenty of room. Before planting, the land should be ploughed deep and put into first-class order. In selecting stock, divide only female plants that produce the finest white plumes. Young hills produce the best plants. From old hills the best plants are obtained around the outside, those in the centre of the stool being mostly worthless unless planted in large clumps. They will produce some plumes the first year, not first size, but worth saving. The second year they ought to produce from 80 to 150 plumes to the hill, if well grown, though not all plantations will do this well. The third year the crop will be about the same. From that time onward the plumes decrease in number, but are larger and finer. At this stage the plants can be improved by trimming or burning away the dead portions. When the plumes commence to make their appearance it is a signal for great activity among those who have large fields, and everything is put into shape, so that there will be no hindrances.

The grass should be so trimmed early in September, before the plumes appear, that each hill may be easy of access. Young plants produce two to three weeks earlier than old ones; and some varieties are earlier than others. It requires exercise of judgment to pick the plumes at the proper time. They are generally ready when they are exposed from the husk a few inches, and have a fluffy look. It is well to try a few at this stage, and if they cure well at the stem end when dry, they are all right, but if they do not fluff up at the stem end they have been picked too young. If the plume looks dark and seedy at the top when cured, it was too old when picked. Some varieties, especially those producing very long plumes, should be allowed to remain somewhat longer on the plant than the plumes of the short producing varieties. By trying a few of each variety that may be in your planting, the time of ripening can soon be ascertained. As the plumes are cut in the field they are taken to the husking-bench to have the husk or sheath removed. This is done in several ways; some pull them out, but if this is not cleverly done much injury results. The best way is to set a knife sufficiently high to split the husk, but not injure the plume; when the husk has been split, a quick jerk or strike on the table will extract the plume.

From here the plumes are carried to the drying-ground, and evenly spread in long rows. This ground should be made smooth and free from any trash liable to adhere to the drying crop. It takes three days and two nights for the plumes to cure, and they should be shaken and turned once each day while curing. They are next packed away as broad and smooth as possible, on wide shelves, in airy buildings.

They should lie there from ten days to two weeks, or until the stems are thoroughly dried, at which time they are ready for market.

In preparing for shipment, one, two, or three grades should be made, according to the market to which they go. If shipped by express, they should be packed in bales of say 2,000 plumes. A covering of canvas or burlap, and some light strips of wood at the corners, will complete the package. If shipping is done by freight, it does not make much difference as to the size of the boxes used, provided they are not less than 4 feet long. A good-sized box is one 4 feet long, 2 feet 2 inches wide, and 3 feet 2 inches deep. A box of this size will hold about 3,000 first-class plumes. If packed smooth and straight there is no danger from tight packing, and very heavy weights can be used. They can be easily restored to their original beauty by exposure to heat and a gentle shaking. The largest demand for the last few years has been from England and Germany.

The Pampas plume is used exclusively for decorative purposes, and when used on a large scale makes a grand display. Many are used in the making of dried grass bouquets, &c. Pretty dried grass holiday cards, in which the Pampas is the chief ingredient, are made in Germany, and sent to California to be sold as souvenirs.—JOSEPH SEXTON, Santa Barbara, in "California Florist and Gardener."—*Gardeners' Chronicle*.

COTTON CULTIVATION IN CEYLON.

The species of cotton which are now in cultivation in various parts are chiefly two, one a native of the Old World and the other of the new. The former species is successfully cultivated in several districts of India and of this the Tinnevely cotton is a fair sample. The other species known as the American cotton is also cultivated in India. Both species claim our attention. A low country, a dry climate and a short rainy season seem to be favourable conditions for the growth of the Tinnevely cotton and for centuries this variety has been successfully grown in South India. Years ago it was grown in Ceylon; and if the cotton industry has of late been almost abandoned among us, the circumstance is due not to unfavourable soil and other conditions of growth, but to the difficulty experienced in finding a ready sale for the produce. One of the European races who in

time's past held Ceylon seems to have carried on a good trade, in local cotton, with the markets of its own country. After its departure, without European patronage, and without such facilities as are in European command, the natives continuing the cultivation found that, for the time and labour they expended on it, they, were not fairly remunerated, and as the only use to which they could turn the produce was a little local manufacture needed occasionally in small quantities, they naturally gave up the occupation, meeting any demand that arose for this article from the semi-jungles of spontaneous growth which are to be found in various parts of the Island, and which are but the remnants of the systematic and extensive cultivation of days gone by.

But the comparative ease of cotton cultivation and the marked success which attended it, seem to have created and sustained, for a long period, a strong liking for it in European cultivators, so that under the British occupation, dating almost from the close of the last century, several attempts were made at revivals of cotton-growing. These efforts were, however, hardly vigorous or calculated to secure any stability to the undertaking. A gentleman here and a gentleman there distributed good varieties of seed, recommended the cultivation, published manuals for the information of growers, or experimented on certain soils in the Island. But thus much and no farther was hardly sufficient to keep up a languishing industry. The cause which at first prevented and discouraged the continuance and extension of this cultivation was not removed; that is, neither Government nor any European agency devised the means of providing a ready market for the produce. The cultivation of coffee absorbed the attention of European colonists, and the great efforts made for it and the labor and capital expended on its cultivation left little or no means and time to push on the cotton industry, so that all interest in it had completely died out by the year 1863.

But of late, with disasters attending the coffee plant and with an exhausted soil, European planters have turned their attention to other products and have invested largely in tea. One of their companies is now vigorously endeavouring to increase the production of cotton, having first wisely secured a mill and all the other necessary appliances for spinning and weaving. Cotton-growing has thus already found warm supporters everywhere on the full assurance that the produce will be found saleable on the very field or at the very door of the village cultivator. With this impulse given to cotton cultivation and the inducements offered to every cultivator, whether the operation be on a small or on a large scale, an inquiry into the experiments hitherto made and the parts of the country best suited for the enterprise becomes opportune and we propose, from time to time, to give details.

The Tinnevely cotton is suited to the dry regions of the Island. It was tried at Anuradhapura. It grew vigorously there and produced its usual crop in less than four months. At Mannar also, it was successful. In the moist regions of Peradeniya and Badulla, however, the plants have been found sickly. Other varieties of seed were also experimented in these moist regions, but with discouraging results. American cotton seems to have been long in cultivation in Ceylon and there is proof that it was successfully grown in Mannar and the North Central Province. One species of American cotton called the "Peruvian" is found almost everywhere in the Island. The seed of this was experimented 7 years ago in the dry regions of Anuradhapura, Vavunia Vilankulam, Mannar and Jaffna with very good results, especially at Jaffna. This experiment was repeated about three years ago, from which it appears, some fine cotton was produced at Mannar and Anuradhapura.

From these experiments two conclusions are clear, first that dry regions are best suited and second that the Tinnevely cotton and the American variety called the Peruvian are more likely to succeed than any other.

Our dry region is very extensive. As calculated

by Dr. Trimen, it covers nearly four-fifths of the Island. This means we have a very large field for the growing of cotton, if we wish to put our hand to it. From the light thrown on the subject by Dr. Trimen's experiments and in view of the great inducements now offered, we would earnestly and strongly urge the great desirability of at once commencing large plantations in the North-Central Province, in the Vilankulam and Jaffna districts and in all our Islands, especially in Mannar and Delft, where cotton was once successfully grown. The conditions of soil and climate which our small coral Island afford seem peculiarly favorable to the cultivation of this product—"Ceylon Patriot."

NITROGEN OF VEGETATION.

Having considered in a previous article Sir J. Luwes' and Professor J. H. Gilbert's evidence by direct experiment as to whether the higher plants or soils by the agency either of micro-organisms or otherwise, fix the free nitrogen of the atmosphere, we pass on to consider the various modes of explanation adduced.

GAINS OF NITROGEN.

- (a.) That combined nitrogen has been absorbed from the air, either by the soil or by the plant.
- (b.) That there is fixation of free nitrogen within the soil by the agency of porous and alkaline bodies.
- (c.) That there is fixation by the plant itself.
- (d.) That there is fixation within the soil by the agency of electricity.
- (e.) And, finally, that there is fixation under the influence of micro-organisms within the soil.

The balance of evidence recorded is considered, however, by the authors to be undoubtedly in favour of the last-mentioned mode of explanation, and that unless there be experimental error, it is pretty clear that there is fixation in the soil, under the influence of micro-organisms or other low forms.

LOSSES OF NITROGEN.

Much of the investigation that has been undertaken in recent years has been instigated by the assumption that there must exist natural compensation for the losses of combined nitrogen, which the soil suffers by the removal of crops, and for the losses which result from the liberation of free nitrogen from its combinations under various circumstances.

The loss by cropping, under the usual conditions of more or less full periodical return by manure, is estimated by the authors to be about 20 lb. per acre.

The loss by drainage, however, is much greater, and in some cases considerable. There may also, under some circumstances, be loss from the soil by the evolution of free nitrogen. Such loss may take place in the manure heap, or in soil very heavily manured, as in market gardening. But in ordinary agriculture such excessive manuring seldom takes place. Loss may also take place when the soil is deficiently aerated. But the balance of evidence is against the supposition that there is a constant and considerable loss by the evolution of free nitrogen from arable soils, which are only moderately rich in organic nitrogen, and which are fairly drained, either naturally or artificially.

A COMPENSATION FOR SOIL EXHAUSTION.

Whether we consider, say Luwes and Gilbert, the facts of agriculture generally, or confine our attention to special cases under known experimental conditions, the evidence does not favour the supposition that a balance is maintained by the restoration of nitrogen from the large store of it existing in the free state in the atmosphere. Further, our original soil-supplies of nitrogen are, as a rule, due to the accumulations by natural vegetation, with little or no removal, over long periods of time; or, as in the case of many deep subsoils, the nitrogen is largely due to vegetable and animal remains, intermixed with the mineral deposits.

The agricultural production of the present age is, in fact, so far as its nitrogen is concerned, mainly dependent on previous accumulations; and, as in

the case of the use of coal for fuel, there is not coincident and corresponding restoration, so in that of the use or waste of the combined nitrogen of the soil, there is not evidence of coincident and corresponding restoration of nitrogen from the free to the combined state.

In the case of agricultural production for sale, without restoration by manure from external sources, a very important condition of the maintenance of the amount of nitrogen in the surface soil, or of the diminished exhaustion of it, is the growth of plants of various ranges and characters of roots, and especially of leguminous crops. Such plants, by their crop-residue, enrich the surface soil in nitrogen.

It is, as a rule, those of the most powerful root-development that take up the most nitrogen from somewhere; and this fact points to a subsoil source. But independently of this, which obviously might be held to be only evidence of the necessity of obtaining water and mineral matters from below, in amount commensurate with the capability of acquiring nitrogen from the air, the experimental results at Rothamsted can leave little doubt that such plants obtain, at any rate, much of their nitrogen from the subsoil.

INHERENT FERTILITY OF SOILS.

Bearing in mind, however, the very large store of already existing combined nitrogen, especially in subsoils, it is important to consider in what way or in what degree this store may contribute to chlorophyllous vegetation?

There is, in the first place, the question whether the roots of some plants, and especially those of certain deep and powerfully rooting Leguminosæ, whose root-sap is strongly acid, may either directly take up organic nitrogen from the soil and sub-soil, or may attack and liberate it for further change, the nitrogen so becoming more available.—*Gardeners Chronicle*.

MANILLA HEMP.

A further report on the Sir W. De Souza machine at the Andamans was received through Mr. Lawrence, Under Secretary to the Government of India, as follows:—"Adverting to the correspondence ending with your letter of the 3rd December last, I am directed to forward a copy of a further report received from the superintendent, Port Blair and Nicobars, on the working of the Rhea Machine in the Andamans, and to state that the Government of India will be glad to be favored, in due course, with the opinion of the Society on the samples of *Musa textilis* forwarded herewith."

Enclosure.

"Letter No. 215, dated 9th January 1889, from the Mechanical Engineer, Chatnam Saw Mill, to the Northern District Officer, Port Blair. In reply to your letter No. 1771, dated 20th ultimo, with enclosures, on the matter of a further trial with the Rhea Machine, I have the honor to report that 95 *Musa textilis* stems 7 feet long were sent in, which were cut into $3\frac{1}{2}$ lengths making 190 in number, the weight of which was when received 1,839 lb.; these were all put through the Machine, the time occupied in cleaning 6 hours, the net result of the whole when thoroughly dried being fibre 74 lb.

2 "During the time of working the vibration of the Machine was very great, so much so that it was dangerous on account of a break-down taking place at any minute. Great difficulty was experienced in keeping the carrying rope tight, and in a great measure delayed the outturn. Before starting the wire rope was covered with hemp, but after being at work one hour, the whole of this was worn off, and it would be advisable that some other more substantial one be substituted. This rope got unshipped while working, and falling between the scraping drum and block broke the machine in three places, this was caused by the centre column which carries the rope turning round and allowing it to get off the wheel; if the holes at either end of this column had been drilled, and not oblong as at present, with the bolts properly fitted, this could not have occurred.

3. "If the result of the present trial is deemed satisfactory, and it is contemplated getting more of the same class, it would be advisable that the Machine should be made of stronger material throughout, as, in my opinion, the material is too light for what the Machine requires to do. It would be also necessary that all the holes should be drilled, and the bolts properly fitted, which would give more stability to the Machine than what there is at present.

4. "It seems to me the greatest difficulty to be overcome is the keeping of the carrying rope in good order. This stretches to such an extent while working, that it becomes extremely dangerous; if a suitable rope could be provided that would stand the great strain, I am of opinion that the Machine would do what is required with safety. A trial with Pineapple leaves and aloes will require to be postponed until a new rope is fitted, as the present one is not safe to use any longer: two samples of *Musa textilis* fibre cleaned are forwarded for approval.

5. "For an experiment as to whether the machine was capable of cleaning Pineapple leaves, 6 leaves were tried, weighing 1 lb., the result being fibre $\frac{1}{2}$ oz., the time occupied in cleaning 10 minutes: these are also forwarded, but as will be seen are not so well cleaned as the *Musa textilis*. On the arrival of the new rope, a further trial will be given to this fibre, and the result submitted as soon as possible."

From the samples received it is evident that the machine does its work effectually, and the yield of 74 lb. of dry fibre in six hours, notwithstanding the difficulties referred to in the report, may be considered satisfactory. The cost of outturn is not given, but were the machine to be in regular work and running 24 hours, the gross outturn taken at $3\frac{1}{2}$ mds. would be valued at say R115 at Calcutta. It seems probable that with permanent arrangements a larger outturn might be expected.—*Proceedings of the A.-H. Society of India*.

COTTON CULTIVATION.

To the Editor of the "Ceylon Examiner,"

Sir,—With reference to Mr. Borrón's communication on cotton cultivation in your last night's issue, may I be allowed to say a few words?

It has been said that Ceylon does not possess a suitable soil for cotton. That the peculiar soil called *Regur*, commonly called the black Cotton soil which overlies a limestone gravel called *Kunkur*, is not found in the Island. This is a mistake, however. Not only does a black soil exist, but it is also accompanied by beds of limestone. This I say from personal knowledge, having found the kind of soil to a great extent in the Anuradhapura District during a recent visit. Black soil is peculiarly suited to the short-stapled Indian Cotton commonly called Tinnevely. Besides the black soil, the two other Cotton soils are known in India, viz. the red and alluvial, and it has been found by experience that these two, especially the red, are better adapted to the growth of American Cotton which is far superior to Indian. I may mention that I saw Tinnevely cotton growing very well on red soil, both at Matale and Maradankadawala, a village in the Anuradhapura District.

Mr. Borrón thinks that the cotton found locally growing is a variety of the Sea Island; but such is not the case. The *Kapu* of the Sinhalese is the Pernambuco or Brazil cotton which, I am led to believe, is indigenous, or if it has been introduced, it has undergone very little deterioration. It grows equally well near the sea and far inland. The peculiarity of this variety of cotton is that the seeds adhere in conglomerations.

The annual system of cultivation is a necessity with the Indian cotton because it begins to die soon after fructification, but our *Kapu* is known to last for about 5 years in Native gardens. If I may express an opinion, I would advise Ceylon Planters to leave Indian cotton alone for a great many reasons, and to cultivate the local *Kapu* and the American and Egyptian cottons.—Yours faithfully, ABA.

INTER-COMMUNICATION ON ESTATES.

A friend, whose visits to our upcountry estates have been few and far between, mentions to us his surprise that so little is done—according to his observation—to overcome the difficulties in the way of communication between the integral portions of upland plantations owing to the natural formation of the hillsides upon which they are mainly situated. He has noticed that it is often a long and tedious climb to get from one part of an estate to another, although the point desired to be reached may be within a stone's throw of the position started from, and yet how to obviate this unnecessary labour is, he contends, a matter both patent and easy. It is all very well, of course, to point out the difficulties—difficulties which no one would be more anxious to remove than the planting proprietors or managers, were it only to save unnecessary labour to themselves—but the question of expenditure is one which would be expected to prove serious on many of our estates were it to be attempted to make "straight paths." Still, while saying so much, we must admit that probably a good deal might be accomplished in the way of bridging the gullies which are so commonly encountered, dividing one part of an estate from another. A great deal of wasted time and labour would, no doubt, be saved if some endeavour were made in that direction, and the needful outlay would probably be recouped within a limited period, by the saving of the superintendent's and coolies' time, as well as by the more constant supervision the former would be enabled to give to the parties working on different portions of such an estate as we have been describing.

We believe that the former proprietors of the well-known 'Bluefields' estate at the foot of the Ramboda Pass had every reason to be content with the result of the expenditure they incurred in bridging a very inconvenient "break" of the above kind on that property. A light iron bridge of 80 feet span was thrown across the ravine, and it must have saved its first cost over and over again by the reduced expenditure in labour, both of men and cattle, which its erection secured. The ironwork of this bridge, we have been told, was prepared in Glasgow and put on board ship at a cost of only £120, and probably that sum was doubled before the bridge was fully erected. Still, when the span of the bridge, 80 feet, is considered, this cost seems extremely small, and it is certainly surprising that the adoption of the same type of bridges in such situations and for similar objects has not been more fully extended than has been the case. But the instance cited is an extreme one. There must be a large number of situations in which bridges of 30 or 35 feet span might be found to yield a considerable economy in estate management. Very few superintendents are aware in the opinion of our professional friend, of how readily obstacles in gullies and ravines may be dealt with and how slight the cost of bridging them can be made. A thickness of three 2-inch planks bolted together—and these planks can be of two or more lengths each—and stiffened with an iron tension rod, or better still a pair of iron bars, will constitute a beam so strong that a pair of them would suffice safely to transport heavily-laden carts. The greater the depth below the centre of the beam at which the bars meet, the less strain there will be on them. The most elementary shilling book on bridge-building would afford the fullest instructions by which an estate carpenter and blacksmith could make beams such as these, and a pair of upright posts on either side of the span is all that would be absolutely

necessary to carry them. 250 to 300 rupees would, it is expected, go a long way towards covering all the cost of a bridge so constructed of from 30 to 35 feet span; and really no more engineering knowledge is requisite than, as we have said, can be gained from the perusal of any one of the several little manuals which deal with the theory and practice of bridge construction. Many of our superintendents, we think, might wisely turn their attention to this matter, and their doing so might result in a considerable saving of labour of every kind and in improved efficiency in supervision. A little reading indeed, we are told, would show that the two types we have quoted—the tension iron beam and the wooden beam strengthened by a tension bar—by no means exhaust the resources which a little pleasantly-gained knowledge would place at their command. A pair of timber trusses to span forty feet would be within the accomplishment of the roughest of estate carpenters if only intelligently directed, and four rough timber piles well sunk in the earth for supports are all that are needed to constitute an efficient abutment, the spaces between each pair being filled in with earth and sodded to prevent slip and wash.

The man who can devise means whereby labour may be saved in the conveyance of produce to an estate store is sure to find adequate reward, and there is scarcely a plantation of any size in our mountain ranges which does not offer some scope for the adoption, with great advantage, of such rough and ready bridges as are thus described. There is undoubtedly somewhat in our friend's observation that insufficient attention is, as a rule, given to overcoming the obstacles which natural formations give rise to on Ceylon hill estates, and we commend his complaint as to this, and the brief suggestions for dealing with it, which we have ventured to summarize, to the notice of upcountry superintendents.

SUCCESSFUL TREATMENT OF GREEN BUG ON COFFEE.

We have the greatest possible pleasure in calling attention to the statement with which Mr. Jackson of the Agrapatana division of Dimbula has just favoured us. We received one or two reports on the experiments made on St. George coffee in the early stages and we certainly got the impression then that the results were not equal to anticipation and barely justified the expense. But it is peculiarly gratifying to learn that in reality, Mr. Jackson sees no reason for dissatisfaction in his experience of fighting the bug, and that the cost was by no means excessive, while he is hopeful that persistence in treatment with kerosene and lime may lead to the complete disappearance of the enemy. The total cost of the treatment—including outlay for kerosene oil, soap, lime besides labour in application—has evidently been reduced to about ten rupees per acre per annum by Mr. Jackson, and at this rate, if only $\frac{1}{2}$ cwt. of coffee crop per acre was saved, the treatment would be worth the undertaking. Our correspondent does not enter into particulars of crops—quantity saved, or additional coffee due to the treatment; but from what he says of the condition of the trees improving, especially from the lime, it is evident that the profit to the lucky proprietors who still own an appreciable acreage of good coffee, from treatment with kerosene &c., may be considerable. Mr. Jackson, in conclusion, refers to the labour difficulty for any extra work such as this treatment of green bug by kerosene emulsion—all hands being required on the

places under his care, for tea. But with our old staple rising in value, and splendid prices even now available for "high-grown Ceylon plantation," we may depend upon it, that labour and material both will be made available by every coffee owner in the country troubled with green bug, to give Mr. Jackson's system a fair trial. Meantime his brother planters, more especially in Udupussellawa, Haputale and Badulla, cannot but feel grateful to him for his cheery while practical note of defiance to their dire enemy. May the "green-bug's" shadow speedily grow less until it disappears for ever!

AN INDIAN PLANTER ON THE TEA TRADE

There can be no doubt that the producers of British-grown tea are paying the penalty of over production in a serious short-fall in values; and that the Chinese tea growers are seeing their revenge in the dragging down of prices all round, by the reckless way in which importers of the leaf from the flowery land have for some time been throwing their large invoices on the market, *without reserve*. This pernicious practice of printing catalogues "for sale without reserve," is an entirely new departure, never having been known before the growers of Indian and Ceylon teas commenced to force China leaf to take a back seat in the Mincing-lane market. Indian planters, however, have thus far struggled manfully against adverse trade, and though they see returns gradually dwindling to very small proportions, they have done their best to meet the emergency by economies in the cost of production whilst Calcutta agents have met them by considerable reductions in charges. They are, of course, limits to this cutting down of expenses, and most of us are of opinion that we have about found bottom in the matter of cost, and that any further drop in prices must involve loss to many shareholders, and the throwing out of cultivation of some of the poorest of the Indian gardens.

As a rather curious commentary on this opinion, I may mention what I have every reason for believing to be true, that in the Doocars district some of the more wealthy companies are making arrangements for opening up large tracts of jungle for new tea cultivation, to the extent of 12,000 acres. There may be some exaggeration in these figures, let us hope there is, but I do not doubt the broad fact of a considerable tea extension. Of course, all this will not be planted up at once, whilst some years must elapse before the new gardens come into crop, and it is to be hoped that in the meantime a corresponding extent of old unprofitable tea acreage may drop out of existence.

The circumstance coming upon a drooping market, renders the opening of new outlets for our tea more than ever desirable. The American tea syndicate has not been formed a day too soon, and this even brokers admit, for they are as much interested in a recovery of prices as are growers. Our teas are usually recognised as possessing great strength; during this and the previous season, however, there have been many complaints in the Lane of an absence of full flavour, in Assams especially, teas being spoken of as wanting in point and briskness. As far as the American market is concerned this fact tells rather in our favour, seen that across the Atlantic, tea drinkers do not care for full flavoured tea, and it is probable that our present make of leaf may suit them to a T.

I notice a great deal of talk about over-firing of Ceylon Teas; the same is frequently cast in our teeth, though I cannot conceive how the reproach has been deserved, for there is as much care taken in Indian factories as was ever the case. Of course these complaints help to depress an over supplied market, but according to my view of matters I consider that the tea importers are much to blame, for, it not selling without reserve, as is the case of China invoices, at any rate over-weighting auctions on sale days without the least regard to the power of the trade to take off anything like the quantity put up. The consequence

is that either many lots are bought in, or sacrifices have to be made, in either case depressing the market.

In consequence of the largely increasing quantities of British grown teas being brought to public auction, it appears very desirable that a further change be made in sale arrangements. In 1890-91 not only will India ship more largely, but Ceylon growers will send about half as much as comes from Calcutta, and it may then be found necessary, not only to have different days for auctions, but different sale-rooms. Indian and Ceylon being sold in distinct parts of the Commercial Sale Rooms.

I suspect the days of 15 and 20 per cent dividends for shareholders in tea companies have gone, never to return. I do not look for more than eight per cent on my shares in a well-managed company. I notice that according to the report of the Darjeeling Company the gross profit for the past year was £9,347, out of which, after payment of commissions to staff and income-tax, it is proposed to pay a dividend of 6 per cent, including £175 taken from the reserve fund. The average price realised for the crop of 1888 was only 1s 0.54d per pound, being 1.44d per lb. below the average price of the previous year's crop. This, it is said, was due to the fact that the weather was unfavourable for the production of teas of fine quality, while a considerable and general reduction occurred in the market values of Indian teas.

I hear some people express doubts about Indian teas succeeding in the States, and they point to the failure of former efforts in that direction. It may not be generally known that the collapse of a very costly American Tea Agency a few years ago was caused by the grave mistake of flooding the wholesale markets with Indian teas, which were recklessly sacrificed at auction instead of being carefully and judiciously placed before the consuming public. We are not going to repeat this costly blunder.—Written for the "Ceylon Advertiser."

NATAL GOLD AND COAL FIELDS.

It would be unfair to criticise too closely Capt. Nicholl's first report as commissioner of mines. That officer admittedly entered upon the duties of his position without special training or experience, while he had before him the work of organising an entirely new department. We shall content ourselves, therefore with simply reviewing the facts set forth in the report. They show that the Commissioner has not been idle. Although he professes to have dealt "more particularly with affairs relating to the gold mining industry and with the work performed by the diamond "drill," he has had other work to attend to. Officers have had to be appointed; rules and regulations to be framed; surveys made, roads constructed and reports prepared. The framing of rules and regulations alone has been a formidable task, beset, as the circumstances of the case are by most conflicting interests and ever-changing conditions, and hampered as Capt. Nicholls must have been by the lack of direct personal acquaintance with the usages of mining industry. One immediate and wholesome effect of gold prospecting has been the extension of roads into the native locations. Three new roads have been opened up to or in the direction of the Umsinga. Whether gold mining pays or not these roads will be a lasting benefit to the colony. On the first point the Commissioner frankly states that "nothing very promising has been discovered, except in the Umsinga Division and in the countries of Umvoti and Alexandra. In these three districts the prospects may be considered as being decidedly encouraging, "several gold-bearing quartz veins having been brought to light, and developed and tested to such an extent as to show that they are capable of proving payable concerns, provided they are systematically worked." The report attributes any delay there may have been in the development of the Natal Fields to the want of capital, rather than to mismanagement or ignorance the other chief factors of disappointment or

failure. The stronger attractions of the Transvaal have diverted from Natal the money that might otherwise have been spent in the colony. There are nevertheless local advantages which favour the successful working of low grade ores the existence of many veins of which character is pronounced to be an "indisputable fact." Of the Fields themselves we are told by Mr. Nevill that the northern—or Umsinga and Umvoti Fields—"differ in many respects from those in the southern portion of the colony." They belong to a later period, and lie in a region that has suffered less denudation than the Umzinto district. They bear a resemblance to the Swaziland Fields. They show few traces of felspar or granite, nor are the veins as a rule "intrusive." The much-talked-of "Golden Eagle," declared on June 19th 1887, exhibited quartz carrying visible gold in considerable quantity. "The reef was cased on both sides with a belt of soft, yellow clay shale, which was also found to carry gold. Seven tons of ore was sent down and crushed in Pietermaritzburg, yielding 56 ounces of gold; but a similar amount taken from the 30-feet level was not, so I understand, a productive. Machinery for the extraction of the gold is on the ground, but has not yet been erected. A water-race from the Ngobevu to the mill site is in course of construction." Eastwood's Reef gave a return of four or five dwts. per ton from a crushing of three tons. Pannings have shown very good results at Mares, where a drive of 104 feet has been carried forward. A tunnel 103 feet has already been driven in from the river bank at the large Umsinga block of 56 claims. An inclined shaft 30 feet deep has proved the presence of auriferous ore at that depth. At the "Try Again" prospecting area a drive 190 feet long has been carried out, and at "Dents" a 77 feet drive is reported. Four other properties are being worked at the Umsinga, but public attention will be more attracted by what the Commissioner has to say concerning "Sinclair's Reef" in Umvoti County, the proprietor having been awarded and paid the bonus of £1,000 offered for the first discovery of gold in payable quantities. Thirteen pennyweights of gold were extracted from a small test crushing, the tailings carrying 5.6 dwts. to the ton. The Commissioners considers, however, that this ore will require special treatment; and it is to be hoped that ere long the means will be forthcoming to crush the several hundred tons of quartz now at "grass." The Umzinto Fields are described by Mr. Nevill in encouraging terms, and at Dumisa's we have the only record of active milling work. The 5-stamp battery opened by the Governor last October has yielded altogether 142 ounces of gold "but there is no reliable estimate as to the amount of quartz from which this result was obtained." As the development and laying out of this mine are now being proceeded with we may hope for fuller results in course of time. The Happy Thought Reef yielded ore which under the Commissioner's supervision gave 10 dwts. to the ton, and 3.6 from the tailing. The other reefs in this district show similarly moderate results from small trial crushings and assays; and the conclusion we arrive at after a perusal of the report—which commands confidence from its matter-of-fact tone, and entire freedom from glow or bias—is that the Gold Fields of Natal are as yet only in an experimental stage of development, and that the results so far obtained are more encouraging than conclusive in their character. It is quite evident that a vigorous expenditure of capital is yet required in order to test the proper value of our local Fields, and we cannot but regret that a fraction of the money that has been lavished, and often squandered, in the Transvaal, has not been spent in the exploitation of these gold-bearing formations within our own borders. There is gold in Natal beyond all doubt, but in what quantity and with what working prospects, have yet to be ascertained. Might not £10,000 or £20,000 of the colony's surplus have been usefully spent in opening up some promising vein both at the Umsinga or the Umzinto? If the results should be favourable the outlay would be rapid with large profit. If they were

not, the knowledge gained would be of manifest value in more senses than one. The public at any rate would have the satisfaction of knowing that the test applied was impartial and trustworthy, being absolutely dissociated from any speculative or selfish interests.

In his references to coal the Commissioner stands on more solid ground. Since Mr. North's report appeared there has no longer been any room for doubt as to the vast extent and excellent quality of the Natal coal deposits. Captain Nicholls wisely takes that fact for granted, and merely confines his comments to the operations of the several companies and properties. It appears from Mr. Hunter's return that during last year the railway Department used 6,250 tons of coal from England's Laagte and 2,109 tons from Dundee. The consumption of Natal coal by other buyers is not likely to have been considerable. What it will be before this year is out we should not like to say. In a few months the Dundee coal deposits will be connected by rail with the sea port, and a new era will at last have been practically entered upon. We are disappointed to find that the operations of the diamond drill on the coast have not so far disclosed any valuable coal seam. Five borings have been made in Victoria County to depths of 392, 248, 322, 117, and 369 feet respectively, but "no seams of coal of any practical value have been met with." At Morewood's Cove the drill was driven to a point in excess of Mr. North's recommendations, without encouragement. At Umhlanga a depth of 739 feet had been reached up to the date of the report. Two or three seams of coal, of a few inches in thickness, were found at a depth of about 500 feet, and as the strata penetrated are of a promising character Captain Nicholls proposes to carry this bore-hole still further; a very proper decision. All inspecting geologists have admitted the possibility of coal deposits being found in the formations lying close to the sea shore, and it is but right, in view of the enormous value of coal seams found so near the port, to make the search on the coast extensive and exhaustive. From a colonial point of view the Newcastle Fields can be left to private enterprise. No one questions their value or the facilities they offer for easy working. The case of possible coal deposits on the coast stands on a different footing. The saving of railway transport along a difficult line would be an enormous gain to the prospects of the industry from a shipping point of view, and the depth of a good seam, discovered, say, fifty miles from the port, would be a comparatively small matter when compared with the reduced cost of delivery at the harbour mouth. We trust, therefore, that the Government will steadily prosecute its boring operations along the coast line, even though it may be found expedient to employ another drill in exploring promising localities further up-country.—*Natal Mercury.*

THE FUTURE OF THE BURMA RUBY MINES.

The name of Mr. Moritz Unger figures so largely in the Blue Books upon the Burmah Ruby Mines, that I was in no way surprised when I received your instructions to interview him upon this interesting subject.

I found him at his residence in the Boulevard Haussmann, and was at once received by him in an apartment, half library, half bureau, that positively bristled with souvenirs of his two visits to the realm of the Lord of the White Elephant.

First and foremost, one of the golden umbrellas that served to mark any one over whom it was extended as a very august personage indeed, and that under the old régime was conferred almost exclusively as is the Most Noble and Distinguished Order of the Garter in our own country—trophies of arms, silks of the richest, a score or two of precious nicknacks from Theebaw's Palace, jewelled playthings of the fallen monarch's children—and I know not what.

"These volumes," said Mr. Unger, opening some bulky, gorgeously-bound and heavily gilt books, "are

sacred books; they are unique—British Museum does not possess their fellows. They are in the Pali language, and in them lie hidden ideas of religion that were in vogue long before Moses went to school at On, or Aaron doffed for the first time his sacerdotal robes."

"I thank you a thousand times, Mr. Unger," said I, "for the very interesting things you have shown me, but if you will allow me to say so, and can spare me 20 minutes, I have come to talk about rubies, and, if you will further permit me, I will put to you a few questions, suggested by a perusal of the Blue Books our editor has sent me. In the first place I find in one of your letters to Sir Edward Buck, Chief of the Indian Revenue Department, you say that the offer you were prepared to make was calculated to add about 400,000*l* per annum to the revenue, and that for an indefinite term of years. The difference between that sum and the four lakhs of rupees offered by Messrs. Streeter is so great that I should like to know what you had in your mind as the base of such an offer."

"I will tell you. I have been twice to Burmah upon this business. Upon the first occasion I was the bearer of letters of introduction to officials of the old régime that secured me a reception from them, and opened sources of information that I venture to say were absolutely inaccessible to others—above all, those coming under the direct protection of the British invaders. Utilising these sources of information, I found that the former lessee from Theebaw paid him one and a half lakhs per annum for the mines, giving up, however, all stones of a value exceeding *R*1,000. About six months before his *déchéance* Theebaw obtained a better price, viz., 2½ lakhs per annum. I set to work to find out what probable profit this lessee and his partners netted, and I discovered that by their charge of 15 per cent upon the value of all stones sent by them to the Ruby Hall at Mandalay, there accrued to them something over 3 lakhs per annum, after paying all expenses and the rent due to the King. Hence I obtained my first item, viz. 200,000*l*, the value of stones yearly consigned to the Ruby Hall. Then I found that by various routes rubies were sent in very considerable quantities to Siam and China by circuitous ways through the mountains to Rangoon, and by special messengers direct to Calcutta, the principal ruby mart of the world. This trade was smuggling pure and simple, and a reliable estimate of its extent could only be arrived at by most searching enquiries. In such a business as Ruby smuggling the 'cutest Chinese must take a back seat to a Burman, and I was not surprised at finding the best informed natives estimated that the value of these smuggled stones very considerably exceeded the total of the recognised trade. I however set it down for the purposes of my estimate at an equal value with the legitimate trade, and so let us call it another 200,000*l*. Let us now add the value of the large stones (*R*1,000 and over) which the lessees were compelled by their agreement to surrender to the King, and take also into consideration those given by them as bribes to the scores of ministers and officials that surrounded him, I will not put this value to figures, nor will I say anything of the hundreds of valuable stones that were buried by the finders and smugglers, except that I know from the numerous purchase I made myself the total must have been magnificent. I will simply say for the moment that I have shown you a reasonable estimate exceeding 500,000*l* per annum."

"Had you any other means of calculating the output of the mines?"

"Yes I had another base of calculation. Under Theebaw there existed in Mandalay a British post office through which there passed rubies to the annual value of about 30 lakhs, 300,000*l*. I estimated the indirect trade before mentioned, the smuggled and buried stones, the bribes and the King's portion; in fact, all those that did not pass through the post office at an equal sum, viz., 300,000*l*, and so I was able to show the friends in Europe with and for whom I was acting, that I was well within the mark in estimating, that under Theebaw's rule and with the primitive methods of working then obtaining the annual yield could not have been less than 500,000

This was taking the rubies at Burmese valuation, which, when I first arrived there. I found to be certainly not over 50 per cent of their European value."

"Then may I take it that you seriously put the total production of the mines under Theebaw at 1,000,000*l* sterling per annum?"

"Well, yes; at any rate I clearly saw that with modern appliances and methods and by the restriction of smuggling and stealing, which would result from adopting the system of keeping the miners in compounds, that prevails on the South African diamond fields (where, as you know, I had a long experience), the mines could easily be made to yield a round million per annum. It was with these facts in my mind, and with the intention (if allowed to tender for the concession of offering the Government 40 per cent of the profits that I wrote the letter to Sir Edward Buck to which you have called my attention."

"Can you tell me, then, how it was that the first concession could have been given to the Streeter Syndicate for such an apparently inadequate sum as four lakhs?"

"Well, to begin with, you must not assume that I communicated to the officials every item of information that I accumulated. In fact, to have simply mentioned some of my sources would have been to have closed them. But I do not profess to have had a monopoly of the power of obtaining information. On the contrary, I think the information that must have been acquired by Col. Sladen during his long residence in Mandalay as political agent would have been simply invaluable at this juncture. Looking back, however, it appears to me that Sir Charles (then Mr.) Bernard went upon the simple plan of taking a rise upon the first bid made him. Messrs. Gillanders, Arbutnot and Co., of Rangoon and Calcutta (a house that has the honour of counting a son of Mr. W. E. Gladstone as one of the members, and who had always extended to Mr. Bernard their political sympathies), were the first to make offers for the mines. They bid ultimately 2½ lakhs, and, as you will see by your Blue Book, were warmly supported by Sir Charles Bernard. Messrs. Streeter's representative, Captain Paton, who had enjoyed the great advantage of intimate acquaintance with Mr. Streeter's personal friend, Col. Sladen, and who was then at Simla, cut in with a direct offer to the Viceroy of 4 lakhs. An intimation of this offer was immediately telegraphed to Sir Charles Bernard who could hardly do less than recommend its acceptance. I protested, as you will see, against this, or any other offer being taken before the Government were in possession of the mines, and before they had had a fair chance of undisturbedly estimating their value—but in vain. Through my legal agents, Messrs. Allen and Vaa Someren of Rangoon, I also offered to send up to the mines at my own expense a competent engineer who should report direct to the Government; but again in vain. Please do not think, however, that I have any personal grievance to establish. Is there anything else you wish to know?"

"Yes, I should like to know whether you do not think that when the company get to work with machinery, they may glut the market?"

"No. Why should they? They have, to begin with, an absolute monopoly, for the true Oriental ruby is found nowhere else. The supply in reserve in their mines is, I have no doubt, practically unlimited, and the former rate of production will be increased, but there is nothing to oblige the company to put out all they might, and they will of course, regulate the supply to the demand."

"What then do you think is the approximate value of rubies that the markets can absorb?"

"The Western markets, Europe and America, can easily take a million pounds' worth of fine and medium qualities without danger of affecting values, while the eastern trade will always absorb an unlimited quantity of the lower qualities. I must tell you that although the far largest proportion of rubies produced are inferior, yet there is always a sure market for them in India and the East, where they are used to inlay jade and other ornaments,

cups, dagger and sword hilts, the saddles and even the harness and trappings, of oriental magnates. Very few people in Europe have an idea of the enormous quantities of inferior and even good rubies that are in demand for these purposes."

"The company's gain must be a proportionate loss to the unfortunate Burmese. What about the 'native rights' that figured so frequently in the despatches?"

"There were no 'native rights.' Anyone acquainted with Burmese affairs, and above all the official, must have known that all property in that kingdom vested in the Crown absolutely and entirely. It has devolved from Theebaw to Her Most Gracious Majesty, whom, as one of her most loyal subjects, I venture to congratulate upon her acquisition; and so I must bid you good day."—*Mining World and Engineering Record.*

VEGETARIANS ON COFFEE.

For some time past an animated discussion has been carried on in the columns of the *Vegetarian* (London, Eng.,) in relation to coffee, tea and cocoa, the use of all three being condemned by many advocates of a strictly vegetarian diet. Many of the views expressed are as novel as they seem ludicrous. For instance, one advocates boiling the raw beans into a thin soup, advocating the plan as follows:—

"The coffee-bean and the cocoa-nib are berries, closely analogous to other beans, and should therefore promise to come within the category of wholesome food. But then it must be remembered that coffee-beans, before they are used, are invariably roasted, which produces a specific change in their chemical constitution. Just as when almonds are burnt, and in the process are converted from a sweet, wholesome food into poisonous material, strongly saturated with prussic acid; so coffee-berries, when they are roasted, undergo a change which is very much for the worse. Were the coffee-berries to be simply boiled into a thin soup, as other beans are, there would probably be but little danger in their use, though in this direction my remarks must be speculative rather than dogmatic.

"I have made some experiments in using the raw coffee beans, but without much success at present. As procured at the grocer's they are singularly tough and tasteless, and require a great deal of mastication before swallowing. Here, however, we are of course confronted by the same difficulty as exists in the case of olives and some other seeds—that it is practically impossible to secure them in England in their natural, fresh, ripe state. Dried peas are very poor substitute for green peas fresh from the pod, and I doubt not that fresh coffee-beans contain possibilities of palatable pleasure, of which we know next to nothing at all. Experiments with cocoa-nibs are much more likely to prove successful; though somewhat bitter, they are not at all unpleasant, and many a legend of Indian warfare goes to prove that raw cocoa nibs are highly appreciated for their staying powers by less civilized, and consequently less critical, gourmets.

"Possibly the issues now contested may resolve themselves into a question of chemical constitution, and that new coffee may be rich with potential blessing for generations yet unborn, as roasted coffee has been heavy with curses for generations yet unburied."

Another regards coffee valueless as to its nutritious constituents and a poisonous article for use, and advocates as a substitute for coffee, as a curative article, "the acorn to be well dried, peeled, cut into small dice half the size of coffee seeds, then roasted, pounded or ground, and infused in the same manner as is coffee."

While a few argue thus, countless millions attest the truth of Lord Bacon's assertion, that coffee "comforteth the heart and aideth digestion."—*American Grocer.*

NATAL COAL.—We (*Herald*) hear that the 10ft. seam exposed on the Hoon River by Professor North on the farm Ballengeigh has been struck in the shaft at the high level, and a large output may be looked for so soon as the railway line is completed.—*Natal Mercury*, May 15th.

THE DEMAND for coolie labour in Fiji appears to be on the increase. There are already many thousands of coolies in the islands, and a vessel has just arrived at Suva with another batch of 600 for the plantations. Tired of the unreasonable restrictions enforced upon them by the Government ordinances, the planters now appear to have made up their minds to depend upon coolie labour alone. To give them their due, the Indians have given great satisfaction in Fiji since their employment has been adopted, and it might not be a bad idea for the Queenslanders to follow the example of the Fijian planters, and have done with all the official humbug which surrounds the employment of the Kanaka.—*Colonies and India.*

TEA CULTURE AND PREPARATION.—**Morningside Rakwana, 14th June 1889.**—1. Mr. Armstrong is responsible for the statement "A strong healthy flush, resulting in heavy pluckings, will give the best tea,"—given before the Maskeliya Planters' Association in August 1885. This is not my experience. I have generally found that the best tea, both as regards strength and flavour, is made during the four to five months previous to pruning. I am of opinion that the flavour and strength of tea commences to deteriorate, if pruning is delayed longer than eighteen months on the hills—by the hills I mean over 3,500 feet elevation—and from twelve to fifteen months in the lowcountry.—2. I have had little experience in the manuring of tea; but from the little I have had my impression is that from manuring—with cattle manure I am only alluding to—the strength of the liquor is improved, but I am very sceptical if the flavour being improved. Manuring with cattle manure forces the trees to give out strong healthy shoots, which, with ordinary care in the plucking and manufacturing, gives improved strength in the cup.—3. I do not believe in fine plucking, but in medium plucking, viz.: the bud or tip, two next leaves and half the third leaf not counting the tip. If these were plucked from every nine to ten days, they should result in good commercial teas. I am very strongly of opinion that the making of good tea begins in the field. If the leaf comes into the factory broken and heated from the pluckers pressing the leaf into the baskets, good tea is, I think, an impossibility. Such leaf gives an uneven wither, and without a good even natural wither, good tea cannot be expected. The flavour, I think, greatly deteriorates if the green leaf is left over the second day in the factory or elsewhere without rolling off, and I also think that from ten to fifteen minutes in the sun to start the wither, and left to cool before putting into the roller, does not hurt the flavour to any appreciable degree. In plucking "strong healthy flushes," the leaf should be weighed at least three times a day, and the good pluckers should be allowed if necessary to weigh their leaf as often as they wish, so as to prevent the heating and pressing down in the small plucking baskets. At the three different elevations, viz.: 300ft., 1,800ft., and 4,000 ft., I have now been tea planting, I have always found that if the leaf is brought into the factory, as it should be brought into the factory, without the leaf being broken or heated or too much handled, good tea with strength and flavour will always follow. Every estate has more or less flavour, but only the estates of high elevation have and can have that delicate and delicious flavour the brokers prize so much. I am certainly not of opinion that the moon when at its full gives flavour to the tea, as one of your correspondents thinks, but I do think that the flush grows much quicker when there is a moon, and consequently is sooner ready to be plucked.—H. R. D.

HINDU ANTHROPOGONIC TREES.

(From the Proceedings of the Agri-Horticultural Society of Madras.)

Read extracts from a paper in the *Journal of the Anthropological Society of Bombay*, by Brigade-Surgeon W. Dymock, B. A., on the "Anthropogonic Trees of the Hindu Castes." During the marriage ceremonies of a Hindu, the branch of a tree is brought into the house, and placed in a *sup*, or winnowing fan and this branch is the first object of worship. The tree used for this purpose varies in different castes. The *Ficus glomerata*, or Udumbara, is also called in Sanskrit *Yajniya*, or sacrificial *Pavitraka*, or purifier. The baton or staff of the warrior or king is, according to the Brahmanic faith, obtained from it; it is a cosmogonic and anthropogonic tree typical of the heavens and of the Supreme Intelligence, the true Bramavriksha, or tree of the Brahmin. The *Ficus Bengalensis* or *Vata*, is also a cosmogonic and anthropogonic tree; it is named *Upasthapatra*. This is the tree of the Roas, who consider themselves, rightly or wrongly to be of Kshatri origin. They pay great reverence to the tree, and will not eat from plates made of its leaves. The staff of the Brahmin is obtained from it. Thus the two highest castes of Hindus make use of fig trees as their anthropogonic trees, and in all Aryan countries the fig tree has, at all times, been considered as pre-eminently the cosmogonic and anthropogonic tree. It is only in countries where no species of fig is found that another tree has been originally substituted for it. The reason of this appears to lie in the peculiar structure of the fructification of the genus, which was thought to produce a fruit without flowers. Possibly in Vedic times it was the only tree used at marriages to represent the phallus, Medha or Mekha also called the *Womshvridhi* or *Kulpalak*, the protector of the family, the principal object of worship during the marriage rites, the *Pramantha* or generative power of nature, which in conjunction with the Shami or *Agnigarbha* (*Prosopis spicigena*), produces offspring or fire.

The Vaishya caste use the *Ashoka* or *Ashapala* (*Saraca indica*) sacred to Vishnu, and worshipped on the Ashokashtami or 8th day of the light-fortnight of Chait (March-April), when it is in flower. Part of the ceremony on that day consists in drinking water in which *Ashoka* buds have been placed. The *Boi* caste of Behar, and the *Sonar* caste use the *Palasha* (*Butea frondosa*); the first are devotees of Kali; the wife of Shiva, also known as *Parvati*, *Bhawani*, *Durga* or *Devi*. They offer a he-goat to the goddess along with the flowers of *Palasha*, the bunches of which are likened to the bloody hands of *Kalis* girdle. The goldsmiths are worshippers of *Shiva* and *Parvati*, and associate its bright-coloured flowers with red gold. *Palasha* is addressed as "glorious," "treasurer of the gods and of sacrifice."

The *Powars*, a tribe of *Rajput* origin, a fire born race, use the *Khadira* (*Acacia Catechu*), a tree remarkable for the hardness of its wood. *Rigveda* III, 35, *Indra* is told to obtain strength by covering himself with *Khadira* wood. The tree is sacred to *Bhawani*, the wife of *Shiva*. The *Marathas* (that is the caste of this name) use the *Kadamba* (*Anthocephalus Cadamba*), as a *Medh*. It is a *Buddhic* and *cosmogonic* tree especially sacred to the wife of *Shiva* in her form of *Durga* and the leaves are offered to her at the *Durga-puja* or *Dassera*. It has orange coloured flowers in the shape of a ball. The *Arka* (*Calotropis gigantea*) is the *Medh* of the *Wadwals* and *Bhandaris*, the first are gardeners, who water and take care of the palm plantations; the second are those who extract the palm-juice. *Arka* or *Arkapatra* having leaves like lightning, i. e., caneiform, is sacred to *Indra*, the *Indian Jupiter*, the god of winds and showers. He is described as strong and drunk with wine, and is attended by the *Maruts* or winds, who roar amongst the forests, and drink intoxicating drinks. The *Wadwals* and *Bhandaris* specially worship *Maruti*, as the well-being of their palm plantations depends to a great extent upon the absence of high winds, and the abun-

dance of water. In the towns of late years many of the *Hadwals* have become educated, and have abandoned *Maruti* for the fashionable god *Shiva*; they have consequently taken the mango for their *Kulpalak*, and follow the customs of the *Pauchkalsbas*, *Sutars* of *Bombay*.

To explain the reason for the use of different trees by all the numerous castes of *India* would fill a volume. To sum up it appears that in every *Aryan* country at least, owing to the analogy between trees and men popular superstition supposes the first men to have sprung up from trees. Children are told in *Europe* that they were found in a garden, or under a goosberry bush; in the *Bundehesh* the first man and woman are said to have sprung from a gooseberry bush. The tree *Ashvattha* (*Ficus religiosa*) is the earthly emblem of the celestial tree, the heavens, or source of *Universal Life*, the real *Baddhidruma*. In *India*, the two higher castes have adhered to the genus *Ficus* as representing the generative powers of nature; other castes have selected different trees sacred to the particular *Deva*, or *Devi* worshipped by them. In *Europe* the *Fig* formerly, and the *May* and *Myrtle* now, are the favourite anthropogonic trees, and though not now worshipped they still retain a symbolic importance. Lastly, we see that several aboriginal or *Mongolian* tribes make use of an animal or metallic phallus.

ERYTHROXYLON COCA.

(From the Proceedings of the Agri-Horticultural Society of Madras.)

Read a paper in the *Kew Bulletin*, of January on this plant, which yields the alkaloid that is so much valued as a local anæsthetic. It appears that the plant was first described by *Nicholas Monardes* in a book published at *Seville* in the year 1580, shortly after the author's death. He alluded to the alleviation of hunger and thirst by chewing the leaves. The stimulating influence of the plant on the nervous system was testified to subsequently by several travellers. The *Coca* is largely cultivated in *Bolivia*, and yields in leaves about 40 millions of pounds weight of a value of two millions sterling per annum, almost the whole of which is consumed in *South America*. The plant has been under cultivation at *Kew* for upwards of twenty years, and from *Kew* hundreds of plants have been distributed to correspondents in different parts of the world. The culture and preparation of the leaves are described at length in the *Bulletin*. In *Peru*, the largest and most matured leaves are sought, as they contain most of the alkaloids which render them marketable. They are dried in the sun, heaped up to undergo a slight amount of sweating, and are then ready for use. Chemical information bearing upon the cultivation of the plant in *India* and the *Colonies* has been contributed to the *Bulletin*, by *Mr. A. G. Howard*, grandson of the late *Mr. J. E. Howard* of *cinchona* celebrity; and other correspondents, including *Dr. Trimen*, F.R.S. of the *Botanical Gardens* at *Peradeneya*, *Ceylon*. Analysis of the *Ceylon* leaves show exceptional richness in crystallizable cocaine; they have no uncrystallizable cocaine, and the total yield is the highest, with two exceptions, of any recorded at *Kew*. Identical results were obtained from leaves grown in *Ceylon* at 1,500 feet, and 3,000 feet, respectively. Other species of *Erythroxylon* are noticed, including the *Erythroxylon Monogynum* (or *Sythia Indica*) indigenous to *India*, known in *Madras* as the *Godara*, the leaves of which were used by the natives to mix with their food during the *Madras* famine of 1877-78. The demand for *Coca* leaves in *Europe*, &c., has fallen off since it has become the practice in *South America* to extract the alkaloids from the leaves at the place of growth, and to ship to the *United States* and *Europe* a crude preparation, containing about 70 per cent. of pure crystallizable cocaine worth about 15s. per ounce, which is largely purchased by manufacturers of *Cocaine*. The *Bulletin* believes that possibly in *India* and *Eastern countries* generally it may still

be worth while to grow sufficient leaves to meet the local demand for Cocaine; beyond this it is scarcely possible to go, if it is borne in mind that South America is able, without further extension of cultivation to produce such enormous quantities of Coca leaves, that the one-eighth part would be sufficient to swamp the Cocaine markets of the whole world. The commercial value in London of Coca leaves varied from 10s. to 1s. 6d. per pound last year.

The attention of this Society was directed to Coca in the years 1885 and 1886, and plants having been successfully propagated from a single specimen in the Experimental Garden, were widely distributed among planters. Small plants are now available. In the year 1885, Surgeon-General Bidie, C.I.E., a member of the Committee, published in pamphlet form a lecture that he had delivered on "Coca, its source, culture, and uses," which threw a flood of light on the whole subject. Quite recently the Board of Revenue instructed the Society to send 100 plants to Ganjam, 50 plants to Vizagapatam, 60 plants to Cuddapah, 40 plants to North Arcot, and 50 plants to Tinnevely.

VANILLA.

Read an abstract in *The Times* of 28th January, 1889, of a recent report by the United States Consul at Bordeaux on the Vanilla trade at that port. One of the most interesting and delicate articles of trade in the Bordeaux market is vanilla, which is imported from the coast of Vera Cruz, the west slopes of the Cordilleras, Java, Mauritius, Tahiti, the West Indies, and other places. Vanilla belongs to the orchid family, and is a sarmentose plant, furnished with thick, oblong, glaucous green leaves. The vine sometimes, attains a height of 45ft. It begins to bear the third year after planting and continues bearing 30 years. Each vine annually produces from 40 to 55 capsules or seed pods, which are gathered before reaching complete maturity between April and June. For one method of preparation they are gathered after they have lost their green tint, and are then exposed to the sun in wollen sheets which have previously been thoroughly heated. They are then put into boxes covered with a cloth, and are again heated in the sun, 12 to 15 hours, after which they should assume a coffee colour. If this is not obtained, they must again be covered and again exposed, the whole process lasting about two months, after which they are packed securely, 50 each, in tin boxes. By the second method about a thousand pods are tied together, and plunged into boiling water to bleach them, after which they are exposed to the sun, and then coated with oil or wrapped in oiled cotton to prevent them from bursting. During the drying process the pods exudes a sticky liquid, which is expedited by gentle pressure two or three times a day. By this process the pod loses about a quarter of its original size. The best quality pods are seven to nine inches in length, and large in proportion, and possess in great abundance the characteristic and agreeable perfume which gives vanilla its value. The vine is sometimes covered with a silvery efflorescence producing an essential salt similar to that found in the pod, and this is diffused on the outside of the capsule. It is called vanilla rime, and is in great demand in the Bordeaux market. Vanilla is used in perfumery, and in flavouring confectionery and cordials. It is supposed to possess powers similar to valerian, while it is much more grateful. Its production in Reunion has increased in the past 40 years from a few pounds to nearly half a million, and that colony is now the principal rival and competitor of Mexico. The total import into France rose from about 200,000 pounds in 1880 to about 260,000 in 1886, but the annual import fluctuates considerably.—*Proceedings of the A.-H. Society of Madras.*

THE SCHOOL OF FORESTRY AT DEHRA DOON, INDIA.

Last year we gave an account of the newly-established School of Forestry at Cooper's Hill, the first of the kind in the United Kingdom, and explained what

kind of instruction was there given, and how it was suited to the training of officers for the Indian Forest Department. We now propose to say something of its brother in India—an elder brother, indeed, by some eight years—the School at Dehra Doon, in the North-Western Provinces, now engaged in the education of those who may, not inaptly, be called the non-commissioned officers of the Department. The Dehra Doon is a long valley, which lies at the foot of that portion of the Himalaya which stretches between the great rivers Jumna and Ganges. It is shut off from the great Gangetic plain by a range of hills called the "Siwaliks," known well to all students of palæontological geology as the range in which were found the wonderful series of bones of extinct mammals described by Messrs. Falconer and Cautley. The valley itself lies about 2,000 feet above the level of the sea, possesses a beautiful climate free from the blasts of the hot winds which, in April to June, sweep over the plains to the south of it; and is further known historically as having been the site of the first experiments made by the Indian Government in growing the tea-plant, experiments which proved its suitability to India, and made the Doon the fatherland of the great Indian tea industry—an industry which has gradually increased to such an extent that the exports of tea from India and Ceylon now very nearly rival in amount those from the Chinese Empire. Centrally situated in this beautiful valley, among plantations of tea, forests of sal-wood, and groves where the deodar of the Himalaya may be seen alongside of the mango, typical of the Indian plains, and feathery bamboos raise their heads from an undergrowth in which wild or semi-wild roses thrive with luxuriance, lies the town of Dehra Doon, the headquarters of a Deputy-Commissioner, of the offices of the great Trigonometrical Survey of India, of a regiment of Ghoorka troops, and of the body-guard of the Viceroy. It is rather a straggling town, like most similar Indian stations; but, centrally situated and surrounded by gardens, is found the Forest School, of which we wish to convey some idea to our readers. The School was first started, in 1878, by the exertions of the then Inspector-General of Forests, now Sir Dietrich Brandis, K.C.I.E., and the first Director was Lieut.-Colonel F. Bailey, of the Royal Engineers.

At present the Director is Mr. W. R. Fisher, B.A. of Cambridge University, who is assisted by a Professor of Forestry, Mr. E. E. Fernandez, and a Professor of Geology and Chemistry, Dr. H. Warth. Mr. Fisher himself lectures on forest botany, while other officers, attached to the School for the management of the adjacent forests, teach mathematics, forest law, forest entomology, and surveying, the teaching of the last-named subject being especially fostered by the presence, in the same building, of the office of the Forest Survey, which is now engaged in the preparation of careful detailed maps of the great forest estate which Government possesses in India, and which bids fair to become, not only by its agricultural and climatic effects, but by its financial success, one of the most valuable of the revenue-yielding departments of the Empire.

Attached to the School is a well-equipped museum, containing a magnificent collection of accurately-named Indian woods; an herbarium, a chemical laboratory, and a meteorological observatory; while the forests of three districts are attached to the School as a training-ground, in which the young students may learn, by personal and actual experience, the conduct of forest operations in the field. The students are usually selected in the different provinces by the Conservators of Forests, and are generally young officers who have seen already some preliminary service.

Several have been deputed by the chief native States, such as Mysore and Baroda, and this shows the spread that an enlightened forest policy is making in the country. There, are, besides, a number of independent students, who study in the hope of obtaining appointments if successful, either in the British territory or in the native States.

The course of study are carried on at the School, the higher in English, leading up to the ranger's certificate, which qualifies the students who succeed

in obtaining it for the appointment as "Forest Ranger," on salaries rising from R600 to R3000 yearly the lower, in Hindustani, leading to the forester's certificate, which qualifies the holder for appointments of from R240 to R480 per annum. The ranger's course lasts twenty-one months, of which eight are spent in theoretical instruction, and the rest in practical work in the field. The subjects taught are forestry, botany, the elements of zoology, chemistry, physics, geology, mathematics, and surveying, with elementary engineering, such as road-making and the construction of forest export works, and forest law. The forester's course lasts sixteen months, four in theoretical study, and the rest in the field, and the subjects taught are elementary forestry and botany, mathematics, surveying and plan-drawing, and departmental procedure.

The students wear a neat uniform of *khavki* drill with a turban or helmet, and they are regularly exercised in drill, most of the European and Eurasian students, however, preferring to join the Dehra Doon Corps of Mounted Infantry. When on tour in the forests on practical instruction, each has a small tent, with furniture of a camp table, chair, and bedstead, and some of them amuse themselves occasionally in sport, one student last year distinguishing himself by carrying off the first prize for shooting in the province.

The forests attached to the School Circle consist of those of the Dehra Doon, Saharanpore, and Jaunsar Forest Divisions. The two former contain chiefly forests of the *sál* tree (*Shorea robusta*), the chief gregarious tree of India, and the most valuable timber for building purposes, after teak. They occupy respectively the northern and southern slopes of the Siwalik Range, and are carefully managed as training forests. The Dehra Doon forests are now being worked under a working plan prepared by Mr. Fernandez, the Professor of Forestry. These forests had, till some twenty years ago, been very badly treated, so that at present the older portion of the stock consists chiefly of trees which are crooked and unsound, the good and sound ones having previously been all cut out to provide sleepers for the East Indian, and Sind, Punjab, and Delhi Railways. The present working plan provides for a temporary rotation of twenty years, during which (1) all the old, unsound, and crooked *sál* trees which can be cut without letting in too much light are removed; and (2) all trees of the less valuable kinds that are not required for shade are cut away. These operations have now been carried on for a few years with the most beneficial results, for the ground is being rapidly covered with good and straight saplings and coppice shoots of *sál*. The forest operations, the selection of the trees to be cut, and their making and enumeration, are all done by the students themselves, so that in this way they obtain a valuable amount of practical experience.

The forests of Jaunsar lie on the hills of the outer Himalaya at an elevation of some 5,000 to 10,000 feet, and consist chiefly of coniferous trees. The deodar cedar (*Cedrus Deodara*) is, of course, the most valuable of these; then come the pines, the "kail" (*Pinus excelsa*), which so often accompanies the deodar, and the "chir" (*Pinus longifolia*), which forms gregarious forest at the lower elevations. The silver and spruce firs (*Abies Webiana* and *Smeethiana*) also occur, as well as oaks (*Quercus incana*, *dilatata*, and *semicarpifolia*) and other temperate trees. These forests are also carefully treated under working plans, and in them the students of the School learn the management of coniferous forests, the extraction of timber by roads and slides, the planting of blanks in the forest, and the measures necessary for protection against fire and frost.

At the end of their course, and on obtaining their certificates, the students return to the provinces from which they were sent, qualified to carry out ordinary forest works in their own country; and some of them have already obtained promotion into the higher staff of the Department as the reward of their good work, industry, and energy.

The Forest School at Dehra Doon may thus be said to be doing an excellent work, a work which

cannot fail to have the best possible effect in the country, and to show the truth of Sir Edwin Arnold's saying that "the Forest Conservancy carried out by the British 'Raj' is one of the greatest benefits to the peninsula."

Soon, perhaps, the extension of forest work will necessitate the establishment of other or branch establishments in Madras, Burmah, and elsewhere; but it is to Dehra Doon that all will look up as the pioneer of scientific forest teaching for the natives of our great dependency.—*Nature*.

EARTHWORMS.—It is interesting to note the fact that at the present time we know of three especially large kinds of earthworms; that, of these, one comes from South Africa, another from the southern parts of India and Ceylon, and the third from the South of Australia. We know as yet little about the distribution of earthworms, but the same laws which governed the distribution of other animals must also have governed theirs, and it is just possible that these great earthworms may be the lingering relics of a once widely spread race of larger earthworms, whose representatives at the present day are only found, as occurs with other forms of life, in the southern parts of the large land-masses of the earth's surface. Possibly careful search will reveal the existence of a large earthworm in the southern parts of South America.—*Nature*.

WYNAD NOTES, June 3rd.—I very much regret that I am not in a position to write particularly cheerfully on planting prospects. In fact many, if not most, of us are sadly disappointed in the result of the really magnificent blossom, which naturally tempted us to hope that a good time was coming at last. In point of fact, with the exception of one or two estates, on which the rainfall was early and sufficient a large proportion of the blossom has totally failed. This is the more extraordinary, as to all appearance it was as healthily developed as possible. In the midst of our own disappointment we have large rooms for sympathy with our brother Planters in Mysore, Coorg, and the Hills. We hear depressing accounts from these districts, and may, by comparison, consider ourselves fortunate. Of course all our hopes now rest on the prospect of continued high prices, and so far the news from home promises satisfactorily. The protracted hot weather has introduced another old enemy, an ancient bogie which had become a well nigh forgotten terror to us. Borer has re-appeared very badly on several estates, but it is hoped that the early monsoon will do something towards destroying this much-to-be-dreaded pest. I cannot understand why planters do not go in more for Liberian Coffee. My own small clearing has been such a success that it is to be extended this year. The trees are wonderfully hardy, and know not leaf disease, bug, or borer. They crop tremendously, and I hear that there is a very fair market for the coffee at home. The disadvantage of it is the difficulty of pulping and curing it. But surely a little ingenuity and perseverance might overcome this. I have two special trees eleven years old and about 24 feet high, which have never had an ounce of manure since they were planted; every branch is covered with crop, and they have never suffered from any of the ills to which the ordinary coffee is liable. I have just heard of an experiment made with Ledger Cinchona which has so far proved very successful. This is *shaving* the trees, as is done with *succirubra*. Hitherto Ledgers have always been coppiced, under the belief that they would not stand shaving, and the trees that did not die of it would deteriorate, so that a second shaving would be useless. The experiment is young so far, and I cannot tell you the result of a second shaving, but the first has been very successful, the percentage of Quinine higher than by the old system, and the trees which were carefully covered do not appear to suffer. The only perceptible effect on them is an enormous blossom, which of course may weaken them. Otherwise they look perfectly healthy.—*Madras Times*.

COFFEE, GREEN BUG AND KEROSENE EMULSION.

Mr. Jackson of Agrapatana favours us with the following further statement on this important topic:—

"Just a line as regards the cost which I gave you for the kerosene emulsion. I see you have reduced my figures to so much per acre, and this, without some explanation, might be misleading. I started with the object that it should be a case of 'hands off' with the bug all through the good coffee, and I simply give, in response to your call, just what it cost us to do this sufficiently to help the coffee to bear the crop then upon the trees, which was a good one, and to keep up as much as possible its condition and prevent the bug spreading. I should say that, perhaps, two-thirds of the total acreage more or less was affected by the bug in all stages, and the balance had little or none at all, and that only the affected trees were operated upon, the others were passed over and small gangs of coolies kept to watch for any after attack. If all the coffee had been badly attacked with bug it would have cost much more than it did, and again the work done easily in the season when the young bug is more easily removed will cost less than when done later on, &c. Of course, those who like ourselves have carried on this treatment—and there are of course a number who have done so (and no doubt with equal results under similar circumstances)—would understand why total cost was given over all coffee fixed upon to be kept clean, &c."

SIR ROBERT HART ON TEA.

It did not need the honours which the Empress Dowager, before she gave up the reins of power, conferred on the ancestors of Sir Robert Hart, to prove to us how highly that gentleman's services are valued by the rulers of China: He has been Inspector-General of Customs for more than a quarter of a century, and in that time he has made as great improvements in the service of which he is the head as have been made in the revenue which that service collects. In the course of his work he has had occasion to call for special reports on a variety of subjects connected with the trade of the country, and none of them have been more complete, if some of them have had perhaps more practical value, than the thick yellow book on Tea which has just been issued by the Statistical Department. It would be impossible to give even the most meagre summary of this interesting compilation in the limits of an article; no paper in it, however, is better worth reading than Sir Robert's report of last August to the Tsungli Yamén, with which it opens. Enclosed with the report are a note and a despatch on the same subject written in 1885 and 1887 respectively. In the note the expected decline in the demand for China Tea is attributed altogether to the deterioration in the quality caused by the belief of the Chinese merchants "that Tea is such a necessary with foreigners that a smaller expenditure of care in its preparation will not lessen the quantity Chinese sell, but will increase Chinese profit," and the Yamén is recommended, in the most straightforward language, to instruct the Southern Imperial Commissioner to call attention to the matter. Two years later the question was becoming more pressing, and Sir Robert goes into it at considerable greater length. In this despatch deterioration in quality and over-taxation are given as the reasons why China tea is being driven out of the English market by Indian. At this time Sir Robert seems to have been of the opinion that it would be a useful step to reduce the taxation on tea. He says—"To a Government, its people's industries must be of a higher importance than revenue; and I would therefore advise that taxes be remitted in order that industries may be preserved; think for the people and forego revenue!"

The Report of August last is the result of more mature and careful consideration, based on the replies received from the Commissioners of Customs at the various tea-ports, the conclusions of their investigations being that there are faults of preparation to be remedied, and that taxation ought to be reconsidered. One disadvantage under which Sir Robert laboured in preparing his report was, that at the time he wrote there was no such falling-off in the export of tea from all China, as would be likely to alarm the Yamén. Between 1865 and 1886 the export actually doubled, and the increase was continuous, except in one year, 1883, the drop then being more than recovered in 1885; so that the Yamén might easily think that the drop in 1887 was also only temporary, though, as we know, it has been accentuated this last season; and this has proved that the Inspector-General was not premature in his warning. He tells the Yamén that Chinese tea is superior in flavour to all other teas—at which possibly the Ceylon planters might demur—and that the decline in its appreciation at home is due to the carelessness of the producers, wedded to their ancient ways and disheartened by falling prices, and to the more economical and painstaking modes of preparation in India. At the same time he does not accept deterioration in quality as a full explanation of the reduction of the demand for China tea in London. "Changes," he says, "have taken place in the trade; for instance the Russians used to buy in London and now buy in Hankow, and the result of the opening up of a sea route is not only that tea goes to Russia direct, instead of through London, but Russian buyers competing for teas have raised prices at Honkow, and, disappearing from competition, have brought down prices in London." He concludes that neither deterioration nor taxation has caused the decline in London, but that it is almost entirely due to changes in the trade.

At the same time he acknowledges that there has been deterioration in quality, and he summarises fully and lucidly the causes of this and the suggested remedies, which we have gone into fully before in considering the reports from the Foochow and Shanghai Chambers of Commerce. That the suggestions will be practically adopted in our time we can hardly hope. The small growers will not be persuaded to consolidate their little patches into large plantations, which might be managed as an Indian plantation is. Mr. Hannen at Foochow and Mr. Chalmers at Tamsui recommend the government to establish model plantations on the Indian plan; but we do not expect to see them started in our time, though the suggestion that the government should send a Commission to study the system adopted in India may possibly be carried out. As to taxation Sir Robert has considerably modified the views he took in 1887. We have more than once remarked that we did not believe that the Yamén would consent to any remission of taxation, and they will fully agree with the Inspector-General on this point. He says: "While to lighten taxation would be of certain and immediate disadvantage to revenue, to do so would be, at least of but uncertain advantage to trade," uncertain because even if the whole 2d. a pound which the taxation now amounts to were taken off, India could still under-sell China. It is not a very powerful argument, but it is probably good enough for the Yamén. The best hope for the trade is that the producers will take more care in preparation, and that the opinion will grow at home that "Indian tea is in some way harmful" to the consumer, "while Chinese tea is not harmful."—*N.-C. Herald*.

How to TOUGHEN PAPER.—A plan for rendering paper as tough as wood or leather, it is said, has been recently introduced on the Continent. It consists in mixing chloride of zinc with the pulp in the course of manufacture. It has been found that the greater the degree of concentration of the zinc solution the greater will be the toughness of the paper. It can be used for making boxes, combs, for roofing, and even for making boats.—*Frank Leslie's Paper*.

Correspondence.

To the Editor.

TEA CULTURE AND PREPARATION:—
EXPERIMENTS IN MANURING TEA.

Brunswick estate, Maskeliya, June 3rd, 1889.

DEAR SIR,—I am sorry that I have been so long in answering your questions *re* "Tea Culture and Preparation," especially as the information I am now able to give about manuring might have made "Practical Planter" come to a different conclusion in his able letter in your issue of the 30th ult.

I now enclose report and valuations of tea made from leaf taken from bushes in every respect similar, except that

No. 1 (808) was manured with cattle manure from 6 to 9 months ago ($\frac{1}{2}$ a basket to a bush), applied in shallow holes between every four bushes.

No. 2 (809) was manured with castor cake and crushed bones 4 to 6 months ago, at a cost of R40 per acre ($\frac{1}{2}$ bones to $\frac{3}{4}$ castor cake) forked in up every other line.

No. 3 (810) was from unmanured bushes from the same field on Brunswick estate, Maskeliya.

The yield of leaf is much greater from the manured than from the unmanured fields, which proves conclusively that it does pay *me* to manure. This may not apply to other districts, or other soils: everyone should try for themselves, on a small scale at first. I enclose replies to your questions *re* "Tea Culture and Preparation," which I trust may be of value to my fellow planters.—I am, yours faithfully,

A. E. WRIGHT.

808. Colombo, 25th May 1889.

A. E. Wright, Esq., Brunswick.

Samples No. 1.

Broken Pekoe.—Blackish, little brownish, small, even tippy leaf. Liquor good body, fine quality and flavour. } 1s 3d to 4d.

Infused leaf bright.

Pekoe.—Blackish, little brownish, well twisted leaf some ends. Liquor good body and quality. } 1s 3d to 1s 1d.

Infused leaf bright a little greenish.

Pekoe Souchong.—Blackish, brownish, rather even twisted leaf. Liquor fair body, good quality and flavour. } 8d to 8½d.

Infused leaf fairly bright a little greenish.

809. Colombo, 25th May 1889.

A. E. Wright, Esq., Brunswick.

Samples No. 2.

Broken Pekoe.—Blackish, little brownish, even twisted leaf, fair show of tip. Liquor good body, quality and flavour. } 1s 2d to 3d.

Infused leaf bright.

Pekoe.—Blackish, little brownish, rather even twisted leaf some ends. Liquor fair body, good quality and flavour. } 1s.

Infused leaf bright, a little greenish.

Pekoe Souchong.—Blackish, little brownish rather even twisted leaf. Liquor fair body, good quality and flavour. } 8d.

Infused leaf fairly bright, a little greenish.

810. Colombo, 25th May 1889.

A. E. Wright, Esq., Brunswick.

Samples No. 3.

Broken Pekoe.—Blackish, little brownish, fairly even leaf fair show of tip. Liquor good body, quality and flavour. } 1s 1d to 2d.

Infused leaf bright.

Pekoe.—Blackish, little brownish, well twisted leaf some ends. Liquor good quality and flavour, rather soft, a little thin. } 11½d to 1s.

Infused leaf bright a little greenish

Pekoe Souchong.—Blackish, little brownish rather even twisted leaf. Liquor good quality and flavour a little soft, rather thin. } 7½d.

Infused leaf fairly bright, a little greenish. }
All these teas have good quality and flavour. In point of merit they stand as numbered.

WHITTALL & Co., per JAS. A. HENDERSON.

ANSWERS TO QUESTIONS.

1. I am not aware that Mr. Armstrong is responsible for the statement "that the quality of the tea is best when the bushes flush most freely; but if he is, I do not think he is far wrong, if from leaf plucked, 6 to 12 months after pruning, and the weather is favourable for a natural wither.

2. I think that manure improves both flavour and strength and increases quantity.

3. I believe in medium fine plucking (*i.e.*, the bud and two leaves, leaving one leaf and the dummy) and plucking round your estate from 8 to 10 days, and think it has yet to be proved that this system will very much reduce the yield per acre, if at all.

A. E. WRIGHT.

3rd June 1889.

THE GREEN BUG ON COFFEE AND
KEROSENE EMULSION.

Eton, Pundaluoya, 4th June 1889.

DEAR SIR,—I have just seen Mr. Cotes' letter in your issue of 31st ult. I have been corresponding on this subject with Prof. Riley (of the U. S. Department of Agriculture) for some months. I wrote to him by the last mail telling him that, although I felt sure from small experiments of my own, that the kerosene emulsion would effectually destroy the bug, there were serious difficulties in the way of its extensive employment; the chief of these being the cost of application. In common with all *liquid* remedies, the cost of transport would, I fear, be prohibitive. The treatment is doubtless suitable for the flat orange plantations of Florida where it is extensively and successfully employed, reservoir carts being used for the purpose. But here on our steep hill-sides the liquid apparatus must necessarily be transported by hand.

It is doubtful whether a single application would be sufficient. Anyone who has paid attention to the subject cannot have failed to notice how rapidly the pest spreads over fields where a few weeks previously not a single insect could be found. The kerosene treatment is not prophylactic, but acts only on the insects with which it comes in contact.

Again—united action would be necessary. It would be useless for one proprietor to clear his estate of the pest if his neighbour refused to do the same. And even should this difficulty be overcome, it would be practically impossible to disinfect the many indigenous plants and trees that at present act as reservoirs of this omnivorous insect.

It might possibly pay to preserve by this method exceptionally good fields in favorable positions, but every other coffee tree on the estate would have to be ruthlessly exterminated.

Under separate cover I forward some of the U. S. Agricultural Department's publications which will give you further particulars about the manufacture and application of the kerosene emulsion. On p. 94 of 'Insects affecting the Orange' you will find a formula for the mixture, and on p. 101 a description of the best methods of application. Figures and descriptions of recent improvements in spray-producing nozzles are given on p. 263 of 'Insect Life.' The nozzle is a most essential part of the apparatus, not only for the sake of economy, but because the finely divided spray forms a perfect mist which settles evenly on every part of the tree.

Prof. Riley is of opinion that this same treatment would prove beneficial as a check to leaf-disease as he has employed it successfully against an allied disease of the vine.—Yours very truly,
E. ERNEST GREEN.

From the works referred to, we quote as follows :—
Soap and Kerosene Emulsions.—The difficulty of obtaining fresh milk in Florida, and the cost of condensed milk, have made a cheaper substitute desirable. This is found in a solution of soap, which forms with kerosene an equally good emulsion. The quantity of soap used in solution need not exceed one-quarter of a pound to one gallon of water, but stronger soap solutions are required to form a permanent emulsion. The percentage of kerosene may also be varied greatly. But emulsions containing over 80 per cent of the oil have too light a specific gravity and are not readily held in suspension in water. On the other hand, in the process of emulsification, kerosene loses a portion of its value as an insecticide, and emulsions containing less than 30 per cent of the oil, although they do not at all, or only very slowly, rise to the surface when diluted with considerable quantities of water, are nevertheless too much weakened for effective use against Scale-insects.

The following formula is considered the best for general use. It gives a wash of sufficient strength to kill the eggs of those species of Scale-insect which are now commonly found in Florida, although in dealing with some of the *Aspidiotus* scales a somewhat stronger emulsion may be required.

Formula :—

Kerosene	2 gallons	=67 per cent.	
Common soap or whale-oil	}	=33 per cent.	
soap			½ pound
Water			1 gallon

Heat the solution of soap and add it boiling hot to the kerosene. Churn the mixture by means of a force-pump and spray-nozzle for five or ten minutes. The emulsion, if perfect, forms a cream, which thickens on cooling, and should adhere without oiliness to the surface of glass. Dilute before using, 1 part of the emulsion with 9 parts of cold water. The above formula gives 3 gallons of emulsion and makes when diluted 30 gallons of wash.

Necessary precautions in the use of Kerosene.—A reckless use of any penetrating oil upon plants cannot fail to prove detrimental. Kerosene is, however, much less injurious than the higher oils, naphtha, benzine, &c., with which, in a crude state, it is associated. The refined oil, such as is commonly used for illuminating purposes, is safer, and should always be used in preference to the lower grades, which contain a large admixture of other oils exceedingly deadly to vegetation.

Effect of Kerosene upon the Orange.—Although the action of kerosene proves more injurious to some plants than to others, a healthy orange tree is but slightly affected by it, and will even support without serious injury applications of the undiluted oil if judiciously made, *i.e.*, applied in fine spray and avoiding exposure of the plant to hot sunshine or to frost before the oil has evaporated. Unhealthy trees and trees suffering from the attacks of Scale-insects receive a shock more or less severe, according as their vitality is more or less impaired. Young, tender shoots, budding leaves and blossoms, are not much affected by kerosene, and may even be dipped in the pure oil with impunity.

The heat of the sun increases to an injurious extent the action of kerosene, and applications of very strong solutions or undiluted kerosene, if used at all, should be made on cloudy days or at evenings.

Milk or soap emulsions containing 60 or 70 per cent of oil and diluted with water ten times are more nearly harmless to the Orange than any other insecticide capable of killing the Scale-insect. Nevertheless the plant receives a shock, imperceptible when the tree is in good condition, but sufficiently severe when it is infested and injured by Scale to cause the loss of the old, devitalized leaves. Complete defoliation and the death of moribund twigs and branches may be expected to occur in extreme cases. The shock is invariably fil-

lowed by a reaction, and in ten to fifteen days new growth appears. The growth is healthy and natural, and if the application has been sufficiently thorough to destroy the Scale-insect, results in permanent benefit.

Enough has been said to show that kerosene is a powerful remedy, perfectly effective and safe if used in moderation, but hurtful in strong doses; that its use undiluted is attended with danger, is entirely unnecessary, and cannot be recommended. In Appendix II will be found an examination of results obtained in experimental applications of kerosene, together with other insecticides, arranged in tabular form for convenience of comparison.

The most favourable season for applying kerosene washes is undoubtedly early spring or as soon as all danger of frost is past. The shedding of the last year's leaves, which takes place naturally after the orange tree has renewed its foliage in spring, is often accelerated by the action of the oil, which is thus made to appear very severe. But the loss of old and devitalized leaves is one of slight consequence, and in the case of badly infested trees is a positive advantage, as the leaves in falling carry with them the scales most difficult to reach with insecticides.

THE APPLICATION OF INSECTICIDES.

Finess and Force of Spray.—In dealing with an enemy so thoroughly protected as are many of the Bark-lice, liquid insecticides should be applied in as fine a spray as possible, or at least in moderately fine spray, driven with considerable force, in order to increase to the utmost their penetrating power. The aim should also be to reach and thoroughly wet every portion of an infested tree, so that no individual Scale-insect shall escape the action of the liquid. This result is not attainable by the old method of sending a jet from a distance into the tops of the trees. An ordinary garden syringe is practically useless. There is needed a force-pump and a nozzle giving a finely atomized spray. This nozzle should be attached to a sufficient length of flexible hose to allow it to be introduced into the top of the trees. The orifice of the nozzle should be directed at a right angle to the hose, and not in line with it. The jet of spray may thus by a turn of the wrist be directed upward or downward, and brought into contact with all parts of the foliage and branches, from beneath as well as from the upper side.

The Cyclone Nozzle.—A nozzle which answers the above conditions and is easily attached to any force-pump by means of a rubber tube is described in the report of the Entomologist. It consists of a shallow, circular metal chamber soldered to a short piece of metal tubing as an inlet. The inlet passage penetrates the wall of the chamber tangentially, admitting the fluid eccentrically, and causing it to rotate rapidly in the chamber. The outlet consists of a very small hole drilled in the exact centre of one face of the chamber. The orifice should not be larger than will admit the shaft of an ordinary pin. Through this outlet the fluid is driven perpendicularly to the plane of rotation in the chamber. Its whirling motion disperses it broadly from the orifice, and produces a very fine spray, which may be converted into a cloud of mist by increasing pressure in the pump. The perforated face of the nozzle-chamber is removable for convenience in clearing the orifice when it clogs. The diameter of the chamber inside need not exceed one-half inch and its depth one-quarter inch. A nozzle of these dimensions attached to the aquapult pump covers one and a half square yards of surface at a distance of 4 or 5 feet from the orifice. The amount of dispersion depends somewhat upon the thickness of the perforated face of the chamber. The diameter of the cone of spray may be increased by countersinking the exit hole and making its edges thin.

Three-eighths-inch gum tubing is sufficiently large to supply one or a gang of several nozzles. The tubing must be strengthened with one ply of cloth.

In use, the end of the hose is supported by being fastened to a light rod of wood, which forms a handle, by means of which the nozzle may be applied to all parts of the tree. For full-sized trees a rod long

enough to reach nearly to their tops must be used. For this purpose a convenient device may be made by passing the small rubber hose through a yellow bamboo rod of the required length. A three-sixteenth brass tube inserted in a bamboo rod has also been used.

Several Applications necessary.—Unless exceptional care is exercised some portions of the bark or leaves will escape thorough wetting and isolated scales will be left alive. The eggs also to some extent will escape destruction and may hatch in sufficient numbers to restock the plant. As a rule therefore, two, or even more, applications will be necessary. A second application should not follow too closely on the first. Sufficient time should be given for the hatching of all the eggs which may have been left alive. On the other hand, if delayed too long, a brood interval will have elapsed and fresh eggs will be deposited. Successive applications should, therefore, be made at intervals of not less than three and not exceeding six weeks.

When the air is charged with moisture, and the nights are cold, with heavy dews or frost, the evaporation, even of volatile oils, is checked, and they remain too long in contact with the plant. Applications made under such atmospheric conditions sometimes prove very severe, and cause the tree to shed all its leaves, or even kill the branches.

COCONUTS A SUCCESS IN RAJAKADALUWA (CHILAW) DISTRICT.

Rajakadalawa, June 10th, 1889.

DEAR SIR,—One of my $3\frac{1}{2}$ -year old trees in bearing! The tree, quite an average one in the middle of a clearing, has had no special treatment whatever, save weeding of course; and though it may be considered by some to be an infantile prodigy, a "sport" of nature or the exception which proves the rule connected with the slow cropping of coconuts,—I take it to be a very indisputable sign of the quality of our soil and the fitness of this region in general for coconut-growing, which I was the first to discern and the first to put under trial. Long flourish the district!—Yours sincerely, GEORGE D. MILLER.

COTTON CULTIVATION.

SIR,—I trust those who are interesting themselves in this cultivation, "both European and native," will not be discouraged by the simple information conveyed by "Peppercorn" and his neighbour "G. P." from garden experiments made on the hillsides of Hantane. No regular cotton planter would think of cultivating on such land.

Let them travel and see the fine healthy patches of cotton now growing on suitable land. We have thousands of acres in the Central, Western, North-Western, North-Central, Southern and Uva Provinces most admirably adopted for cotton cultivation. Only careful attention is required to secure a profitable return.

There is not the least doubt that it will become a valuable industry to the natives.—Yours,

TRAVELLER.

COFFEE:—GREEN BUG AND KEROSENE TREATMENT IN THE AGRAPATANAS, DIMBULA.

St. George, 13th June 1889.

DEAR MR. EDITOR,—I have already gone through a deal of correspondence about my treatment for green bug, and a good many have been over at different times and seen the results for themselves.

I read the letter of Mr. Cotes with much interest and was quite prepared to hear that the "Kerosene Emulsion" had destroyed the bug wherever

it was applied; but I have certainly no experience myself beyond this:—nothing that I have tried has succeeded by first application in both destroying the bug and keeping it away for the future. With me it has regularly returned each season fat and flourishing; but I am glad to say it has not spread so rapidly or to the same extent, the last two seasons, as previously; and that the trees treated for bug seem to stand the attacks better now than at first, and I think it probable that the pest will gradually leave us. I notice you say that "good results were obtained for a time, yet experience did not prove it to be such a case as would warrant general application or repay all the outlay." I really do not know how you arrive at such conclusions; for whatever doubt there may have been in the early experimental stage, there can be no doubt now that the treatment carried out on these estates has been very successful. The cost has been anything but excessive and perhaps much less than many would think.

The first year's cost was the heaviest, and I give actual figures of this on one of the estates as follows:—

187 acres, lot of coffee besides in tea:—labour cost R1,322.81; lime cost R453.39; kerosene oil and soap &c. cost R82.98: total R1,859.18.

On another estate it was—98 acres, and a lot of coffee in tea:—labour cost R710.27; lime cost R428.71; kerosene emulsion cost R59.01: total R1,197.97.

This is for the full 12 months, which means two general attacks upon all affected trees right through, and then several gangs of coolies being kept on to watch for any return of the bug and to wash it off wherever it appears.

This year the cost is considerably less. The lime is altogether an extra, but I have found it very beneficial to the trees after being treated for bug, and it helps both to ripen up the crop and to keep up the condition of the tree. The above 287 acres are well cultivated coffee and have been regularly manured. I found however that the highest cultivation of itself could not withstand the severe attack of bug which we had at first, and that equally good coffee side by side with this 187 acres and 98 acres—to which we did not apply the kerosene emulsion but which had extra manuring—utterly failed to keep its condition or to ripen its crop to any extent.

The application in my case is a very simple one. The cooly has a rough piece of cloth which he soaks in the kerosene oil mixture and rubs over the bug wherever it is to be found (I do not wash the stems of the trees), and this means sudden death. In the early life of the young bug, I have found even water will remove it; but when older, it takes a good strong rub to unbinge it. The details of application are easily worked out, each one for himself. I believe a great deal of valuable coffee might have been saved had the kerosene emulsion been carried on more generally.

The difficulty at present is to spare labour with such demands as tea makes upon us just about the time that the bug begins to put in an appearance: so that any plan giving equally good results, which could reduce the labour required, even at an increased cost, might be valuable. W. J.

GRAIN TAX SETTLEMENT, MATALE, AND PADDY CULTIVATION.

14th June.

DEAR SIR,—Mr. King's report with diagrams is very clear and should show the Executive how to treat the policy of the acting A. G. A. who now wishes to restore all the tanks in the two korales, Innamulawa and Kandepola, where the paddy crop is only given at 5-fold; most un-

profitable return and what no Kandyan would ever think of cultivating for. Just fancy Government going to spend R50,000 on a tank called Iraula where some 25 families are at present in healthy condition and their total land under the tank "when restored" would not exceed 400 acres! Innamulawa is the north-east corner of Matale district, having for its north and east boundary the N.-C. Province; Sigiri is in this korale. The people live by hunting and chena cultivation. I fancy it will soon become the finest Crown forest in the Central Province.—Yours, HUNTSMAN.

MR. ELLIOTT'S EXPERIMENTS IN PADDY CULTIVATION.

Nuwara Ehiya, 17th June 1889.

DEAR SIR,—Referring to the interesting letter on the subject of paddy cultivation from Mr. Elliott in your issue of the 15th, will you allow me to point out that Mr. Elliott omits from his calculation the salary of the two instructors who carried out the experiments and apparently the cost of watching, upkeep and supervision during the seven months that the crop is ripening.

Add these items, and I venture to think the profit will become a vanishing quantity. Thus, taking the Galle instance:—

Mr. Elliott's nett profit ..	R64
Deduct cost of watching, upkeep and supervision, say one man per diem for 7 months at 32c.	R67-20

Nett profit

--Yours faithfully, C. J. R. LE MESURIER.

A NORTHERN PLANTER ON COFFEE.

DEAR SIR,—Mr. Jackson's communication on the treatment of green bug is very interesting. But have you not heard of how to catch birds by putting salt on their tails? Rubbing the coffee branches infected with green bugs with a rough cloth steeped in kerosine may do good or rather harm to these pests, but I should think the rubbing, if fairly done, even without the kerosine would be equally efficacious. But what about the coffee leaves? for I have generally seen them as badly affected as the branches, or more so; are they all rubbed too with a rough cloth soaked in kerosene? I am afraid coffee must be allowed to die in peace, though it, like the coffee planter, is dying hard.

NEW PRODUCTS.

[We suppose Mr. Jackson can reply that his "rubbing" and *lining* has not only saved crop, but maintained the vigour of the tree. We suspect with present prospects that if "New Products" had 100 acres of decent coffee he would do a good deal even to lengthen its life?—ED.]

LONDON TEA CIRCULARS: BLUNDERS.

SIR,—In Messrs. Gow, Wilson & Stanton's tea circular of May 24th there are given the averages of some 110 Ceylon estates or marks. And in 55 cases the average differs from that given in Messrs. Wilson, Smithett & Co.'s circular of same date. In one instance there is a difference of 1½ and in several instances a difference of 1d per lb., which is sufficiently large to be annoying to

THOSE CONCERNED.

PLANTING IN BURMA:

A FUTURE ELDORADO FOR PLANTERS.

Tavoy, Burma, 18th May 1889.

DEAR SIR,—Tavoy news at the present moment is rather alarming. We have here just now the Commissioner, Col. Plant, who has tried the rebels

brought from Siam: 9 are to be hanged and 14 transported for life, so that we shall be clear of some 23 notorious characters. I fancy we have now got at the bottom of the whole affair and will for the future live in peace. I am sending you W. B. Hudson's letter, and I trust you may publish it. You will observe that it was rather hard on his party, who had gone all the way to Mandalay and from there down the Chindwin river and found no one to show them the *land of promise*. Such treatment at the hands of Government is a disgraceful shame, and gives a decided blow to any ready enterprise, and any planter could readily feel Mr. Hudson's disgust. Mr. Hudson is one of the leading planters in India, and a smart business man; and well-known to a good few in Ceylon.

The rains are on again, and everything is responding both bud and blossom. I have shipped over 50 cwts (of coffee) which is now on voyage per S. S. "India" to London.—Yours faithfully,

JAMES D. WATSON.

(From letter of Mr. W. B. Hudson, C. I. E. on Burma.)

We left Rangoon by rail and proceeded through such a country as I have hardly ever seen the equal of for fertility, and we soon realized the field there is for the pioneer in Burma. Miles of teak and other hard-wood forests interspersed with open savannas of *lime* grass higher than a man's head. Hardly a human being to be seen except here and there in the hamlets of raised wooden houses, very few cattle or buffaloes, but many temples on the plain, the banks of streams and on every hill. Thousands of acres of the richest black cotton soil, loam, and laterite lying waste, except where a small patch round the houses is cleared and sown in rice, tobacco, oilseeds or cotton—and such cultivation! The merest scratching of the Tirhoot village plough would have been superior in many cases, and it appeared that our informant spoke the truth when he told us that in many places, after having burnt down the scrub and grass, they turned their buffaloes on the plot after the first heavy rain, and trampled the land until they had *pouched* it into a state fit to scatter the seed rice over it. Then they left it "severely" alone—no weeding—until the crop is ready to be cut. Fancy 25 maunds per Tirhoot bigha with such tillage as this. What will not virgin soil do? On seeing this fertility one of the reasons for the pest of the country—dacoity—breaks on the observer. As long as the rural population can buy a couple of months' labour secure enough to live on for the remainder of the year, why should they work? The young bloods must have something to amuse them, besides wrestling, boxing and making love. A little dacoity, in which there is often more "cry than wool," must be a godsend to them.

The country is divided into valleys by long broken ranges of mountains which appear in some places as high as five or six thousand feet. To suit yourself for the cultivation of any particular crop you have only to choose your site at the proper elevation. I need not attempt to describe the forest. Its magnificence in some places is almost appalling. It struck me at once that the wonder is not that dacoits are not caught, but that *one ever is* in such a country. On the line of rail we passed Mr. Mylne's grant which was pointed out to us by Mr. Gouldbank, his manager. The settlers say the land will produce anything, and that the climate is better than B har, and the children appear to get on all right—which is an infallible test of climate. Clearing the forest they say is slow work, but the crops of rice and rahar they get the first year at once puts life ("dam") into them. The dacoits try now and then to frighten them, going so far as to fire shots into the manager's bungalow, always at night of course. However, as they take good care never to come to close quarters, we don't even get up now, but turn over and to sleep again.

Past Toungoo through miles and miles of forest with mountain ranges on either hand in the distance, and here and there a hamlet called a "town." Houses all wooden raised on piles, and many handsomely carved and decorated, the lazy inhabitants allowing the jungle to grow right up the door steps in many places. More temples than houses. Past several "cities" in which the striking object is always the huge golden temple surrounded by a troop of smaller ones, always on the most picturesque sites. The people, even the peasantry, all clad in silk, the women's garments more especially of the gayest colours, and both men and women always happy looking and ready for a laugh. Kyoukse district is the first in Upper Burma in which we saw any considerable area of cultivation. The irrigation works appear to be complete and are said to be very ancient. The people are said to raise three crops of rice in the year off the same land, and certainly we saw the crop in all stages along the line, from that just sown to the stubble just cut. After three days' stay at Mandalay, the "barbaric magnificence" of which I will not attempt to describe, Mr. Walker and I set off by steamer down the Irrawaddy to see lands which were available for settlement. However on arriving at the place there was no one to show them to us, and although we saw hundreds of thousands of acres of land lying waste, tree-forest, grass, mountain and alluvial plains miles in extent, which would grow anything, "we did not catch that whale, brave boys," and beyond having a most interesting trip we did nothing. The long voyage down the river from Sagaing to Prome was a pleasure trip. Portions of the river remind one of the Rhine on a grand scale, others of the Lower-Ganges and Bramaputra churs. I cannot attempt to take up your space with descriptions of the scenery or the people, but must stick to my subject, *viz.*, the capabilities of Burma for colonization by Beharis. On our return to Rangoon, I had an interview with the Chief Commissioner; and asked him to consider on what terms Government would offer grants of land to Behar planters who would not be afraid of dacoits! and would settle in Upper Burma where the climate is more like North Behar than in the Lower Province, bringing with them any Beharis they could influence to accompany them. Sir Charles Crosthwaite promised to consider the matter.

On the whole subject the conclusions I came to were:—(1) That it was desirable to see the country in the rains as well as the dry weather before settling on a location; (2) That the terms at present offered by Government were not good enough to tempt Europeans; (3) That nothing but large staples such as rice, wheat or perhaps cotton would pay a European planter in Burma for probably a generation to come; and (4) that the idea of growing indigo, tea, or tobacco there, or in fact anything requiring much labour may be put down as folly.

I will conclude with an incident which amused me. On a road just outside Rangoon some Madras coolies were making a drain. I asked them what they were earning a month. They said about Rs. 16. I also found a *Kurmi* from Oudh amongst them who was loud in his praises of the country. It was about sunset and the "ganger" passed the word to stop work. My friends wiped the clay off their *kodalis* with their feet, went out into the middle of the road, hailed a *ticca gharry*, and drove home.

COTTON CULTIVATION IN CEYLON.

Colombo, 20th June 1889.

DEAR SIR,—I am sorry to have to inform you that the new shoots growing up from the old shoots of my American cotton planted on Jack Tree Hill have been attacked by green bug. This attack, which is doubtless owing to the very wet weather for some time back, seems to indicate that in specially moist districts it is not expedient to leave the shoots of old plants in the ground through the monsoon, but to resow for each crop. The Egyptian and Tinnevely cotton planted on Jack Tree Hill do not at present show any signs of being affected.—
Yours faithfully,
JAS. BLACKETT.

CEYLON TEA AT HOME.—A Londoner writes by last mail:—"I hope your tea prospects are good. The island as a whole seems to be producing a quantity of leaf, all sorts of wonderfully funny names being advertised, and packages displayed in the shop windows. I like the tea."

SHADE COFFEE.—Mr. Primrose writes to us from Coorze:—"I was pleased to see the notice regarding the advantages of shade which appeared in the *Observer*. No one now ever plants coffee in these districts without it, and it is worth trying in Ceylon, especially at 3,000 feet or under."

A CURIOUS COCONUT TREE.—A gentleman who was down at Matara the other day tells us of a curious coconut tree he observed on the roadside a few miles beyond Galle, which bore ordinary coconuts on the one side, and king-coconuts on the other! Though he has been travelling about the island for a good many years he does not remember either seeing or hearing of a similar case before. Neither do we, and we should be glad to hear more about the history of this curious tree.

A TEA CASE.—Judgment was given on Thursday, 30th instant, at the Southwark County Court, in a case of considerable importance in the Tea trade. The defendants sought to establish that, although they had taken part delivery of certain Tea, and paid for such portion, they were at liberty to decline the remainder; and further, that it was the custom of the trade to advance the duty on Tea, and forward it to the buyer, without the option of asking for the amount of duty in advance, in cases were it was considered desirable. Judgment for the plaintiffs with costs was given on all the issues.—*Home Paper*.

ENCOURAGEMENT FOR TEA IN AMERICA.—Mr. A. S. Stanton (Gow, Wilson & Stanton) writes to the London Chamber of Commerce Journal in respect of an extension of the use of tea:—

The fact that in the United States nearly 90 million pounds of tea are now annually consumed, whereas 20 years ago only 40 million pounds were consumed, speaks volumes, and this is only one out of many instances which might be cited. It is probably only through individual enterprise that the successful introduction of tea into new markets can generally be accomplished; and it should not be forgotten by those trading with foreign countries that the unprecedentedly low price to which tea has fallen, furnishes an opportunity for its distribution which is more favourable than any that has previously occurred.

Adaptation is considered necessary, as the *Statist* puts it:—

Of course, the United Kingdom stands far and away at the head of tea-consuming countries, followed by the United States and Russia. Considering the population, a very large quantity is taken by the Australasian Colonies, and an appreciable amount by Canada. The consumption per head is largest in the Australasian Colonies and New Zealand, the latter taking the lead with 7.65lb. per head, followed by the Australian Colonies with 7.50lb. per head. India is developing trade with Australasia, but still the bulk of the tea consumed even by those Colonies is derived from China. So far as the United Kingdom is concerned, the expansion of consumption of British grown tea in the Australian Colonies will give us no direct benefit, as shipments will be made direct from India and Ceylon still it will give us an indirect benefit in the employ of shipping, increasing the spending power of the planters who buy from the mother country, and giving dividends on English capital employed in the cultivation of tea in British possessions. In the United States we may expect a development of consumption of India and Ceylon growths provided the planters suit the tastes of the market. In case the United States consumers "take to" such teas, the United Kingdom will secure a more direct benefit, as the tea will pass through this country.

CUTTING DOWN EXPENDITURE IN TEA.—We learn that orders have been given in a few cases to suspend the weeding of certain tea fields. Regular monthly weeding is of course one of the biggest items of expenditure as carried out on a Ceylon plantation; while in Assam it is only attended to periodically, sometimes once or twice a year. There is room perhaps for experiments in lowcountry fields with good soil; but past experience is not in favour of a suspension of clean weeding, although it has been proved that the tea bush can hold its own against weeds.

COTTON-GROWING IN THE EASTERN BINTENNA DISTRICTS.—The attention of Sir Arthur Gordon and his Government may well be called to the letter of Mr. E. Woodhouse in another column. If the facts be as he states and he writes to a certain extent from personal knowledge, we feel sure that the two Government Agents—Messrs. Elliott and Fisher—at present responsible for the Vedda districts will be ready to do all in their power to carry out successfully any orders of Government for the resuscitation of a cotton-growing industry among the people. Free grants of land and a free distribution of seed might well be allowed under certain guarantees for the cultivation of the same being duly carried out, in order to secure a fair start.

COTTON-GROWING AT THE SEASIDE, PANADURE.—A correspondent writes:—"I send you a sample of cotton I found growing on the seaside line near Panadure railway station and not a hundred yards inland from the seashore. The variety is different from anything I have met upcountry, the pods, leaves and seed being smaller and the staple of the cotton good and of a silkier texture. Kindly let me know if it is a good marketable variety. The trees or bushes were about 10 feet high and several years old. The seeds in the pods are enveloped singly in wool and not attached to each other in a cluster as in the variety we have in Uva. Please let me know what variety of cotton this is called." Messrs. Darley, Butler & Co. report that the above is the poor Tinnevely cotton, which ought not to be encouraged here in cultivation, there being so many better kinds available. For instance, the "ratakapu," which is already so freely spread throughout the island, and which our present correspondent knows in Uva. This good kind, we learn, has also, curiously enough, been found growing almost at the door of the new Cotton Mills in Wellevatta.

COTTON FOR THE LOCAL MILLS.—It is certainly encouraging to learn from the Secretaries that the new Mills will be able to offer up to 40 cents a lb. for fine cotton; a rate which leaves a fair margin even for the European planter, if as Mr. Blackett reckons he can gather 135 lb. of cotton an acre (as an adjunct to other cultivation) at a cost of 15 cents per lb. Still, 40 cents per lb. is not equal to the 1s to 1s 9d per lb., Mr. Blackett spoke of as home valuations. However, on this point as well as on what the local Mills can do, it is well to give some interesting information afforded us in answer to enquiry:—

"We shall probably have to commence with Tinnevely cotton (got from Tuticorin), (1) because we have not got cotton enough here yet, (2) because the hands must work up gradually to finer counts than can be spun from Tinnevely. It will spin 20s yarn, and a little over. We want kidney, New Orleans, and the like, to spin up to 40s; some of this number we shall use by itself, and also with lower counts, according to the fabric. Sea Island we can afford to buy some of and *misc. Fine white* Sea Island may be worth the prices you name, but for a long time, I expect to find much of our cotton grown here, stained &c., and Liverpool people make heavy deductions from prices for that."

COFFEE AND GREEN BUG.—Mr. W. B. Jackson, an old experienced planter, noted for his steady application to duty and moderation of statement, affords a very encouraging report in our present issue of his fight with "green bug" on a large extent of coffee under his care in the Agrapatana division of Dimbula. We are hopeful that this will lead all other planters with fair coffee in their fields, though troubled with bug, to make a good fight with this pestiferous enemy and endeavour, if possible, to overcome it. The proprietors who have crop on their trees are, in view of good prices in prospect, certain to do all in their power to secure the maturity of their cherries.

NEW AND OLD PRODUCTS.—Our planting community are eager enough about adding one or more products to their tea fields, and it will not be for want of variety that they may not make a choice. In addition to tobacco and cotton, about which so much has been said and numerous experiments with which are now in progress, there is a selection of spicetrees, nutmegs and cloves especially, besides pepper, ginger and vanilla in which a good deal may be done. Our new Manual, very nearly finished, on "ALL ABOUT SPICES,"—with well-executed engravings more especially to guide in treating the vanilla plant—should be a great stand-by to the planter. Those of our tea planters who have not rooted out their coffee although stumping the bushes to the ground, are now beginning to encourage the old staple again. "Suckers" are to be induced to grow, and there may be some sprinklings of crop gathered in this way, to back up tea. Among new products, the latest recommended is the "Fig" for culture, and it is likely to be tried over a considerable extent, good seed being about to be introduced, while the suitability of the soil and climate of our hill-country for the fig has long ago been proved. There is no reason why figs (a most wholesome fruit) should not add considerably to local food supplies, if indeed an export trade is not likely to prove profitable.

COCONUTS AT VEYANGODA.—The topic of most interest in our little community at the present time is the change that will take place on the Naivel Coconut Estate shortly. The lease was sold yesterday to one Paulis Silva of Mattakkuliya, who is described as a wealthy plumbago merchant, for Rs.200 per annum for 4 years, and subject to very stringent conditions. I wish the new lessee joy of his lease, and hope he will not forfeit the ample securities he has to deposit. For the last 16 years the lessee has been Mr. Edward Poulter, a nephew of the late Mr. Lorenz. He was as widely and well-known as a hard-working and practical planter as a good sportsman and crack shot. Many of the European and Ceylonese gentlemen from Colombo who always found a welcome under his hospitable roof, and who hunted with his fine pack will, I am sure, regret his severance from an estate in which he was resident for so long. But he is not to leave the district, for apart from his proprietary interest in it, Mr. Millen, the object of whose visit to the island was so greatly exaggerated, has fortunately secured his valuable and efficient services for the mill he is about to start. I congratulate Mr. Millen on the happy choice he has made of a manager. It would have required a deal of travelling to find a more practical, hard-working and honest man than he has secured, and one who knows the place and the people so well. From all I hear Mr. Millen is not going to work oil mills, buy up coconut estates or plant them. He is simply going to prepare coconuts in a form known in confectionary and cooking as desiccated coconut I believe. What the mills are for is kept a secret. Land for the mills has already been secured in the neighbourhood of the station, and material for buildings has already been brought to the spot. Success to you and your undertaking, Mr. Millen!—Local "Examiner."

Mr. W. J. FORSYTH, formerly of Maturata, Ceylon, and who has since travelled about a great deal—has at length, we learn, settled down in Guatemala to open up and cultivate a large coffee estate of his own. We wish him all success with our old staple and it will be of interest to learn whether the leaf fungus or bug troubles Mr. Forsyth's trees and how he is off for labour.

COTTON CULTIVATION.—We trust Mr. Blackett will respond to Mr. Holloway's challenge in respect of the profitable character of cotton cultivation in his experience. Of course it is quite possible that cotton, which may be shown to be scarcely worth cultivating by Europeans, may prove a fairly profitable industry for natives. But in Mr. Blackett's case, his splendidly fine crop was valued so highly that it could scarcely fail to be profitable?

PLANTING IN BURMA.—We call attention to Mr. J. D. Watson's letter and extract from Mr. Hudson's Report given in our page. The latter once more shows what a splendid country Burma is bound to become when cultivation extends over her splendid alluvial soil; but fortunately for the present generation in Ceylon and other parts of the East, that time is not yet—labour is very scarce and means of transport difficult. Men now-a-days fight rather shy of pioneering work such that which Mr. Hudson indicates.

EXOTIC TIMBER TREES.—The Assistant Conservator in the Central Province (Mr. Alexander) has distributed a circular to planters all over the hill districts, which, if duly responded to, ought to be the means of bringing in very useful information. It contains a "Table showing comparative growth, &c. of exotic timber trees, place of growth in district, province, elevation, rainfall; also giving the name of trees, their native country, height, girth, age, how planted, aspect of soil, general uses, with remarks." The trees specified with their habitats are as follows:—

Eucalyptus Marginata, jarrah, Western Australia; E. Rostrata, red gum, East Australia; E. Diversicolor, karri pine, West Australia; E. Globulus, blue gum, Tasmania; E. Obliqua, stringy bark, New South Wales; E. Paniculata, iron bark, East and West Australia; E. Resinifera, red gum, New South Wales; E. Robusta, mahogany gum, East and West Australia; E. Longifolia, brown gum, West Australia; E. Gunnii, Tasmania; E. Calophylla, red gum, East and West Australia; Acacia Decurrens, black wattle, Victoria and N. S. Wales; A. Melanoxydon, black wood, Victoria and N. S. Wales; A. Dealbata, silver wattle, Victoria and N. S. Wales; A. Pycnantha, golden wattle, Victoria and N. S. Wales; A. Longifolia, Victoria and Tasmania; Araucaria Excelsa, Norfolk I. pine, Norfolk Islands; A. Cunninghamii, Moreton Bay pine, Queensland; A. Bidwillii, Bunya Bunya tree, Queensland; A. Cookii, Cook's pine, New Caledonia; Biota Orientalis, Chinese arborvitae, China and Japan; Casuarina Quadrialvis, the sheoak, South Australia; C. Equisetifolia, swamp oak, Eastern Asia; Cupressus Macrocarpa, large coned cypress, California; C. Torulosa, bhutan cypress, North India; C. Sempervirens, common Cypress, Persia; Cryptomeria Japonica, China and Japan; Cedrela, Toona, Indian swamp cedar, India; Calliandra Samen ingasamen, South America; Cedrus Deodara, Indian cedar, North India; Frenela Robusta, rocky bay pine, Australia; Grevillea Robusta, silky pine oak, Queensland; Pinus Longifolia, long-leaved pine, Himalayas; Pinus Insignis, the remarkable pine, California; Myroxylon Pereire, Balsam of Peru, Salvador; Jambosa Vulgaris, rose apple; Malay Archipelago; Eriobotrya Japonica, loquat, Japan; Tinstania Conferta, Queensland; Tectona Grandis, teak, India, Burmah; Swietenia Mahagoni, mahogany, Central America.

SUGAR CULTIVATION IN INDIA.—Few people have a proper idea of the extent to which sugar is produced in India almost entirely for home

consumption. The area under cane is estimated in the latest official report at 2,500,000 acres yielding on an average of coarse sugar, 20 cwt. per acre—so that the total crop is equal to 2½ million tons of sugar. But this is not all. Apart from the cane, an immense quantity of sugar (jaggery, &c.) for native use is made from the palm-trees, more especially the date, in Central and Northern India, the palmyra further south, and only very little from the coco-palm which scarcely extends beyond a fringe on the shores of Travancore and Cochin. The statistics of area under palms are however manifestly imperfect: an account giving for all India:—

Date palm	168,262 acres
Palmyra "	14,100 "
Coco "	2,930 "

while another report gives for Madras alone

Coconuts, dates and palmyra 29,800 acres.

And there must certainly be more than 2,930 acres of coconuts in all India. An article on this subject from the *Pioneer* we have marked for our *Tropical Agriculturist*.

TEA CULTURE AND PREPARATION.—Direct answers to these three questions, I am not able to give, but as a contribution to the discussion on the questions involved would say:—

1. If the inquirer has been following any particular line of advice, and think he is aggrieved, he surely knows best who is responsible to him and in what way.

2. That to have tea leaf in paying quantity is of greater importance than either strength or flavour and that to get leaf in such quantity on many patana and old coffee soils will not be possible without the help of some kind of manure. The opening up of such soils while applying the manure will enable the roots to reach the subsoils on which so much of our hope depends much sooner than they would otherwise do.

3. The question of quantity or quality can hardly be decided even so far as Ceylon is concerned until we know how many pounds of poor Chinese quality has been made fit for sale by the blending with it of our superior quality. And if we did know this surely it would be better for us to send quality to that amount, as well as the corresponding amount of quality required to blend with it—as long as the cost of production and sale was covered—rather than continue to bolster up the China trade by sending quality only.—N.

INDIAN MUSTARD OIL.—It is suggested by correspondents of Indian journalists that merchants in the Agra district, which produces large quantities of mustard seed, should form a syndicate, purchase the oil-pressing mills on sale in Bombay and Calcutta, and prepare mustard oil on a large scale for export to London. The oil-cake could also be exported, though a good deal would be consumed as cattlefood in India. A hundred pounds of mustard seed, advocates of this scheme say, give from 34 lb to 36 lb of the oil, hence 300 lb of seed has to be sent to England to produce 108 lb of mustard oil. It is therefore manifest that sending the oil in place of the seed is the most profitable from of procedure. To promote this project the merchants should advance money to the cultivators to grow pure mustard and cress crops. The common garden cress yields a superior culinary oil, and is very easily cultivated. One hundred pounds of cress seed will give 57 lb of oil; thus 200 lb of cress seed gives as much oil as 300 lb of mustard seed. If the Assam tea planters would press and export the mustard-seed oil, and retain the oil-cake, it would supply them with an excellent manure for tea plants. The cress could be easily sown between the rows of tea plants, now taken up by growing weeds and grasses, notwithstanding the spring deep hoeing.—*Chemist and Druggist*, May 25th.

[To grow a green crop to be buried before seeding is a mode of fertilizing: to grow plants for their seeds would exhaust the soil and injure the tea bushes.—Ed.]

TOBACCO PLANTING IN SUMATRA AND BORNEO.

Tobacco cultivation continues to spread in the neighbouring countries. For instance, that raised from Deli seeds has proved a success in the Lampong districts. In the S. E. division of Borneo, the people have energetically turned to cultivating that product, especially in the district of Amunthay, but, so far, only for home consumption. There is every prospect of a change there ere long in this respect, owing to the attention of speculators being directed to the advantage of investing European capital in this line of business. The article will be raised for the European market. Already, preliminary measures have been taken to lease land for the purpose.

In East Sumatra itself, this branch of cultivation continues to progress, a steady increase in the number of estates being noticeable. In Deli, last year's crop came fairly up to expectations. The reverse was the case in Siak, where the yield proved unsatisfactory. In both districts, land, which had lain fallow from six months to 13 years, has been extensively brought under cultivation with varying results. Where fertilisers had to be resorted to Peruvian guano and stable manure have preference. The disturbed condition of western Langkat and Tamiang has prevented the Government from throwing them open to European planting enterprise.

A correspondent of the *Deli Courant*, writing from British North Borneo, draws a dark picture of the outlook there. For instance, lately, during 4 to 6 months at a stretch, Kudat and Maruda Bay, he says, had hardly any satisfactory Government supervision. In the latter, the desertion of coolies from estates is common enough. When they happen to be caught, a rare event he insists, the lightness of their punishment and their easy life in the prison house render the penalty anything but deterrent.

The "Sumatra" may count upon a large quota of passengers from the Deli planting community, owing to the few attractions presented by the land they live in. Society there offers few pleasant features. The landscape and scenery come into prominence for unsightliness. Lallang grass, abandoned tobacco land, brushwood, and stretches of tobacco fields pass monotonously before the traveller's eyes, varied by long vistas of half-burned trees. Plantains are the only fruit the country produces. Such a country offers no charms to planters accustomed to more civilising surroundings. Those who have made their pile are only too anxious to quit it for fairer lands.

An interpreter for the Chinese language named Hoetink has been despatched by Government to Swatow to devise measures for facilitating Chinese coolie immigration from there to Deli. It has taken the planters there a long time to arouse the Government to a sense of the advantages attending such a step.—*Straits Times*, June 7th.

BARK AND DRUG REPORT.

LONDON, 30th May.

CINCHONA.—At today's auctions several packages of Huanoco bark, imported via Hamburg, sold at 6½d to 9d for thin and broken to fair quill; good flat Maracaibo was bought in at 9d per lb, dull mossy split Loxa quill at 1s 6d, and Lima at 8½d per lb. Small flat Calisaya sold at 1s 4d per lb. The exports from Java to all parts in the periods between July 1st and March 31st have been as follows:—

	1888-9	1887-8	1886-7	1885-6
	Amst. lb.	Amst. lb.	Amst. lb.	Amst. lb.
Private bark	2,782,322	2,181,265	1,234,753	814,449
Government bark	558,712	511,823	501,600	398,675
Total	3,341,034	2,693,088	1,736,353	1,153,124
„ English	3,675,131	2,962,396	1,909,988	1,268,436

CINNAMON.—The quarterly auctions held on Monday were exceptionally light, comprising only 1,505 bales quill, and 275 bags chips. There was a very good demand indeed, for the better grades of quill cinnamon, which generally realised from 2d to 3d per lb advance, and also for chips. Cinnamon third and fourth class quills, however, sold at some decline. About 1,270 packages, all told, were sold, were disposed of at the following rates:—Ceylon quill, fine and extra firsts 1s 1d to 1s 7d; ordinary to good ditto 7½d to 1s per lb; extra fine seconds 1s 2d to 1s 4d per lb; low to fine ditto 7d to 1s per lb; thirds, common to very fine 6½d to 1s 3d; fourths 5½d to 11d per lb. Tellicherry quill, firsts and seconds 8d to 8½d; broken 5d to 6½d per lb; Chips, broken to good quillings 4½d to 6d; ordinary 2½d per lb.

COCA LEAVES.—Eleven bales good bright green but broken leaves were shown today, and bought in at 1s per lb. A parcel of 150 packages of what are returned as "cocoa leaves" have passed Southampton in transit from Bahia, in Brazil.

OROTON SEED.—Seven bags small dark Ceylon sold today at 9s 6d per cwt. Two bags (140) oroton-seed bark from Venezuela in bold thin pale yellow pieces were withdrawn.

ESSENTIAL OILS.—Several lots of Cinnamon oil were shown today, but no sales were made. Citronella sold at 3d per oz., the same price as at the last auctions.

QUININE.—The market must again be quoted lower, and we hear, and there is not much reason to disbelieve the report, that 2,000 of second-hand B & S were sold at 11½d per oz this week, while others talk of a transaction at 11½d per oz. spot. A sale of 20,000 oz of the same brand is said to have been made at 1s per oz for forward delivery. The B & S agents would probably also submit offers at 1s per oz. The other makers' quotations are uncertain.—*Chemist and Druggist*.

INDIAN TEA ANNUAL REVIEW.

30, MINCEING LANE, June 1889.

The statistics just published for the twelve months ending 31st May show an increase of 8½ million lb. in the Receipts, and of 5¼ million lb. in the Deliveries of Indian Tea; while of Ceylon Tea the Import is 11½ millions larger, and the Delivery 11¼ millions more than in the previous years.

Regarded in the abstract these figures are encouraging—more so, perhaps, to Ceylon than to Indian producers—but the development has unfortunately been accompanied by an adverse movement in prices affecting both crops—Ceylon rather more than Indian—for which the larger yield is not an equivalent.

Seeing that the increase of 20 millions in tea of British growth has been coincident with a decrease of 17 millions in the receipts from other sources, and has, therefore, added less to our total supply than the larger trade has absorbed—the year's consumption being more than the year's supply—the shrinkage in value cannot be attributed merely to over-production, and the cause must be sought elsewhere.

The poor quality of the crop has undoubtedly contributed to lower the value; but a part from this, producers are suffering from the growing aversion of the dealers to be the stockholders—the state of business affording them but little encouragement to do so; and it seems obvious that, if the onus of carrying the stocks be thrown upon a section of the trade unready to bear it, prices must suffer. It should be borne in mind that, when China tea was the leading article, its value more or less governed the market for tea in general; but the China merchants, as a body, retained the means of regulating prices to some extent in times of undue depression, by private sale, and by not compelling the dealers to carry the stock. Indian and Ceylon teas, however, now lead the market; and as importers for the most part find it to their interest to sell at auction on arrival, prices are practically regulated by the demand of the day; it is, therefore, of primary importance not only that those in the trade should be encouraged to buy with more confidence, but also that additional buyers should be attracted to the market by the prospect of remunerative employment of capital.

An appreciation of this, and the desire to lessen an objection which keeps many from buying who would otherwise be disposed to invest in tea, prompted the recent alteration in the mode of printing catalogues; an experiment which apparently works well, though not carried out so completely as was first thought desirable.

Passing to a brief retrospect of the season—at the opening, buyers were hindered from acting with freedom

through having on their hands stocks of high cost tea of the old crop, unsaleable except at a heavy discount; by the inferior quality of early arrivals; and by the expectation of a large addition to the supply from India and Ceylon without any assurance, at that time, of a short export from China. On the other hand, the very poor quality of the new China Congous, and the fact that prices opened and were for some time maintained at a level out of proportion to merits, served to emphasize the cheapness of Indians, and prepared the way for their increased consumption. The expansion has since then been continuous; but it has not been sufficient to prevent stocks from accumulating, and this in conjunction with the pressure to sell, and the unattractive character of the larger portion of the supply, has led to a range of price for many kinds low without precedent.

In our last year's Review we remarked that "the experience of many seasons shows that whenever supplies of low teas are plentiful they sink to a price which leaves little if any margin for profit." Another season has unfortunately proved the permanence of this elementary principle. There is, however, some compensation, giving prospect of a much better delivery than last year during the summer months, which will lighten the trade's holdings, and leave them more readily to operate in the new crop—especially if it should prove to be a good one. In a season productive of so little fine tea, those who aimed at making special and distinctive qualities have naturally reaped the full benefit—indeed, the fine teas made throughout the season, notably in Upper Assam and at the close in Darjeeling, have realized prices almost equal to those of former years. Should there be any general return to the plan of making smaller-crops of higher grade, quotations for fine teas would probably recede from their present level after the first three or four months; still, allowing, for this, we maintain the opinion that it is best for those who cannot secure such a yield as will bring down cost to 6d per lb. to aim at quality before everything else. Especially is this advisable in Darjeeling, for no tea has yet been grown to displace the finer produce of this district, and its limited quantity will always ensure it a market; whereas, inferior Darjeelings, together with Terai, Dooras, and Chittagong teas, have more reason to fear the competition of Ceylon than the produce of Assam, Cachar, or Sylhet, whose strength or pungency give them a more distinctive character. Were the policy of making rather less tea, but of better class generally adopted, both in Ceylon and India—the reduction in supply which would result, and the enhanced reputation of the crops, would go far to put the trade in a better position.

It is most satisfactory to discern a growing enquiry from foreign markets, especially from the States and Canada, where the merits of Indian tea are unquestionably obtaining recognition, while the low prices are attracting buyers.

When time has removed the prejudice attaching to every new article, and the organized endeavour to introduce it is in full operation, we are hopeful of a trade growing by degrees in volume until it is sufficient to affect us as perceptibly as the export orders influence the market for certain sorts of China tea.

Estimates for the coming season point to a supply of 140 millions, or possibly 145 millions, from India and Ceylon; and of 5 millions from Java. Our requirements should be about 225 millions, leaving 75 millions for China to contribute—24 millions less than last year, which is a heavy reduction to hope for. The shipments from China should therefore be closely watched, and as well as the reports from London as to their quality and price.

By permission of proprietors and managers we publish the results of many estates for season 1888-9.

STATISTICS FOR YEAR ENDING 31ST MAY.

		1889	1888	1887
Import—	Indian	94,954,000	86,371,000	78,200,000
	Ceylon	26,390,000	14,705,000	8,060,000
	China	98,695,000	117,185,000	138,900,000
	Java	4,170,000	2,989,000	3,494,000
	Total	224,209,000	221,250,000	228,654,000
Delivery—	Indian	91,368,000	85,619,000	75,425,000
	Ceylon	22,830,000	12,578,000	7,744,000
	China	105,668,000	116,870,000	134,300,000
	Java	3,862,000	3,133,000	3,671,000
	Total	224,728,000	218,200,000	221,140,000
Of which	Home Con.	185,250,000	183,000,000	180,000,000
	Export	39,500,000	35,200,000	41,140,000
Stock—	Indian	27,755,000	24,115,000	23,517,000
	Ceylon	7,194,000	4,618,000	2,184,000
	China	37,350,000	44,400,000	43,100,000
	Java	1,284,000	914,000	1,054,000
	Total	78,583,000	74,047,000	69,855,000

The following statistics show the development of the Ceylon trade:—

SUMMARY OF TRANSACTIONS AT PUBLIC AUCTION.

	Total	pkgs., amounting to lb.	Average price about
1888-89	381,500	26,500,000	10½d per
1887-88	227,000	13,600,000	1s 0½d "
1886-87	124,600	7,500,000	1s 1½d "
1885-86	73,500	4,800,000	1s 2½d "
1884-85	37,400	2,500,000	1s 3d "
1883-84	22,800	1,500,000	1s 4½-10d "

Our previous Table showed the following results:—

	Acreeage	Quantity lb	Price per lb
1887-8	60,000	22,664,000	1 0 1-20ths
1886-7	56,300	21,500,000	1 0
1885-6	53,137	19,000,000	1 0
1884-5	49,283	17,000,000	1 1 4-7ths
1883-4	48,663	17,000,000	1 2
1882-3	43,815	15,000,000	1 ½

WM. JAS. & HY. THOMPSON.

CEYLON AT THE PARIS EXHIBITION.

The Ceylon Tea-room is at the west base of the Eiffel Tower, facing the gardens and picture galleries, and occupies a space of 120 square metres. The front is a magnificent carved wood screen of Sinhalese design, prepared by Mr. Smither, late Architect of the Government of Ceylon. The counter is in the same massive carving—plain and bold, without any colouring or gilding. There is something very pleasing in the design. The walls are covered with tapestry, the top being a yellow band on which are depicted the sacred animals of the Sinhalese. Ceylon tea is sold in cups and in pots, the latter being preferred by the connoisseurs. Ceylon coffee, most delicious Ceylon cocoa, chocolate and other light refreshments are to be had. Three of the native servants who were at the Glasgow Exhibition are present, and much admired, being handsome, merry boys, fond of laughing and showing their white teeth. The work, which is very well done, was executed by Messrs. Amedee Joubert & Co., King's Walk, Chelsea, who have also built and decorated the Indian Palace, the Australian and New Zealand Courts, and the Wine Pavilion in the Trocadero grounds, &c. The Tea-room is daily becoming more and more popular as a resort, between the hours of 4 and 6 p. m., where the wearied visitor can obtain a cup of most refreshing Ceylon tea, and in the evening after 9, it is a very favourite place from which to view the illuminations.—*Colonies and India*, June 5th.

FIG CULTURE.

We call attention to the following paper on the culture of the fig. Some of the most delicious figs we have ever tasted have been grown in Ceylon, and the tree has a wide range, since, while Uva seems to give a perfect climate and soil for its growth, the tree flourishes and fruits mature in Maskeliya, Dimbula and even in Nuwara Eliya, while no doubt the same may be said of Kandy and Matale districts. An advertisement elsewhere refers to the procuring of seed of the best kinds of fig; and as a result of the attention now called to the subject we trust to see not only a beginning—that has already taken place—but a considerable extension of fig-growing in different districts of the country. Few, if any, fruits, we suppose, can be more easily preserved for the European markets, although the demand locally and for passing steamers ought to be considerable. In the name of the planters—not the prophet—we emphatically say, Figs! The paper referred to is as follows:—

THE CULTURE OF THE FIG.

In Syria, though not generally known, the fig tree (*Ficus carica*) has for ages flourished to perfection. Not only is this tree productive of one of the most luscious and healthful fruits grown, but in its season it may be seen with its spreading boughs weighted

down with a prolific crop that would astonish those who raise it in this country under glass or in the open air. Figs are never so enjoyable as when partaken of fresh plucked from the parent tree, although, of course, from necessity, those from the East only reach us in their preserved or dried condition. Green figs—by which I mean fresh gathered figs—are only to be had for a few weeks each season, and are mostly grown in the Channel Islands, Guernsey also paying special attention to their culture, whilst around Worthing, on the South Coast, they are also raised in quantity. A few from the South of France and Spain reach the English markets in small flat wooden boxes, holding as a rule from nine to fifteen fruits each, and are, when sound, very sweet and enjoyable.

To the food reformer figs are invaluable, inasmuch as they are full of medicinal virtues, and so nutritious as to enable people to live well upon them for months when eaten with dry bread. I have made many a delicious meal off them, with nothing else than a piece of bread and a raw apple or two, and always found myself in the best health, strength, and spirits in consequence. An old physician, writing a hundred and fifty years ago, says, "Not only are figs nourishing, but they quench thirst, are good against the stone, resist poison, and agree with any age or constitution, and are prizeless as a medicine and food."

Smyrna sends us a tremendous quantity of this popular fruit. The cultivators simply gather the figs when ripe, scatter them round the trees, and allow them to dry in the sun, when they are ready for exportation; and when we remember that in one year, lately, Smyrna exported 21,600,000 pounds weight of this fruit alone, it will be seen that this crop is an important one with the natives.

The culture of the fig is simple, and may easily be made to become a profitable industry. The productions of the forcing house and those raised under the shelter of wall, and otherwise in the open air, always—when well grown—meet a ready demand at profitable rates. Two kinds are grown—the white and the black—and although the former are certainly far sweeter than the latter, yet they are not so popular with the public, presumably on account of their size—the black being twice as large, at least, and of better appearance. Both kinds are very prolific even in this country, and in the Channel Islands I know of one tree from which is produced, season after season, extraordinary crops. In Florida and California especially, they are laying down thousands of trees in consequence of the success which has already attended their culture there.

The cultivators plant them at the rate of one hundred trees to the acre, from which, when full grown, they obtain over two bushels of fruit from each tree. The supply is not equal to the demand, and, in consequence, they realise at the rate of £40 nett per acre from same, and at this price it pays the growers exceedingly well, and more so when we remember that one man can manage ten acres of such fruit easily, except during the picking season, when extra help is necessary. Very few fruit trees require so little care or attention, and very few can be said to pay better. It should be well known, especially after the good work that has been done through the powerful influence of *The Weekly Times and Echo*, that beneficial results must, and always do, follow in a remarkable manner the free use—especially in the spring—of fruit as food.

Fruit is in itself a perfect food when fully ripe, and, used in conjunction with other things, it will be found that we shall be less liable to suffer from gout, gallstones, and kindred affections.

Next to the destructive use—or, rather, abuse—of drugs, more sickness and disease is caused by the use of improper food than from any other cause. Man violates the laws of life and suffers in consequence; but if we regulate our habits, our diet, and our life, and take into the system, with other things, a plentiful supply of citric, acetic, and malic acids, through the medium of fresh, ripe fruit, we shall find that we are not only enabled to secure good health, but prolong life.

SAMPSON MORGAN.

TEA IN AMERICA.

NEW YORK, May 25th.—An investigation in this city has shown that the warning to American tea drinkers, sounded by United States Consul Crowell, stationed at Amoy, as to the shipment from China to this country of much worthless trash, has an excellent basis. Notwithstanding salaried Federal tea inspectors a vast quantity of such stuff has been admitted here, and is selling at 15 cents per pound.

The *New York Commercial Advertiser* comes out today with an interesting article on the New York Tea Trade. It observes:—"Whilst all kinds of tea are drunk in the United States the consumption of particular descriptions would seem to follow certain parallels of latitude. Thus a line drawn from Albany, New York, westward, would indicate in the regions north of it the area in which Japans are chiefly consumed, this area including Ohio and Michigan. In Chinese teas the chief domestic trade is in Oolongs, but, judged by a series of years, Japans appear to be steadily gaining ground. The higher classes of Oongou are favoured by the aristocracy of this city, many of whose members, it may be assumed, acquired a taste for it, and appreciation of its sedative properties during summerings in England; but the large mass of tea drinkers throughout the country prefer teas such as Oolongs, Greens, Japans, and mixed with their more stringent and excitable qualities. A moderate export business is carried on from New York to Mexico and elsewhere, these teas being consumed mainly by foreign residents. The consumption of tea in the United States is extremely moderate, the yearly consumption being at the average rate of one and a-half pound per head.—*Cor., L. and C. Express.*"

HILL-COUNTRY PLANTING REPORT :

GOOD PLANTING SEASON—PRICE OF TEA SEED—DEMAND FOR PEPPER CUTTINGS AND CULTIVATION ON AN EXTENSIVE SCALE—PUSHING OF TEA AMONG NATIVES.

24th June 1889.

So far this season has been a good planting one, and the results are likely to be favourable. Those who are putting out tea say very little regarding it, and they go about their work with a lack of enthusiasm. There is more energy displayed by the men who have seed to sell, and it is interesting to notice how well the advertised price keeps up. If there is one thing a planter hates more than another, it is a falling market, and he never agrees to lower his price with a good grace. Still even the advertised prices for seed are creeping down, while the quality of the seed, if anything, is improving.

Pepper cuttings are being put out here and there, and in some cases on rather a large scale. Those who have pepper in bearing tell me that they are quite satisfied with the price which the local demand alone allows them. By-and-bye this local demand will be overtaken, and in time, we will overtake the world's consumption, with—shall I say the usual results?

There seems a demand for dust, congou and red leaf among the natives here and elsewhere, judging from the applicants who are prepared to buy. One man told me he sent it to Southern India for sale in the bazaar. Then, another had Jaffna as a field to work in. The Jaffna man retails his chest by the brew: a cent or two are charged for enough to make a strong cup of tea in the morning, and it will pay handsomely at that.

It is pleasing to hear of new markets being opened anywhere! Certainly if the millions in the plains of the Carnatic would take to tea-drinking—and get their produce from Ceylon, we are in a position to supply it. Would it not be a good thing for the Tea Fund to engage the services of Mr. Borron for a crusade there in favour of the natives drinking tea?

Lectures might be delivered in populous village centres, elementary at first, confined say to the marked advantages to digestion of drinking hot water, with tea in it. I believe in the long run this would pay no better than selling it to our coolies, to which I don't think any of us take at all kindly.

PEPPERCORN.

THE FUTURE OF CINNAMON: THE NEED OF SUPPRESSING CHIPS.

We can do no more in view of the late hour at which his letter reaches us, than call attention to the important communication in which Mr. Jardine of Negombo deals with the above subject. The letter has been written, we believe, very much at our suggestion and from his long experience and position as manager of perhaps the leading cinnamon plantation in the island, there is probably no one more capable of advising his brother planters to apply a remedy for the low prices of their staple. Proprietors—native gentlemen especially—will only have themselves to blame if they decline to adopt and follow Mr. Jardine's advice, should the recent unprofitable state of the market be continued and even intensified, by the further shipment of "chips."

GEMMING AS NOW CARRIED ON IN SABARAGAMUWA.

EXTENSIVE GEMMING OPERATIONS AT RAKWANA—ABANDONED COFFEE LAND TURNED INTO GEMPITS—OPERATIONS SUSPENDED ON THE EVERTON ESTATE—BOWITIYATENNA A SCENE OF LIFE AND HAPPINESS—ABOUT 1,000 SINHALESE AND MOORS AT WORK—THEIR 'MODUS OPERANDI'—THE NATIVES PREFER TO PAY THE OWNER OF THE LAND ONE-FIFTH THE SHARE OF THE PROCEEDS—DISHONEST GEM-MINERS—THE FIND OF A VALUABLE SAPPHIRE BY A RANGWELLETANNE ESTATE GOOLY WOMAN—A EUROPEAN GEMMING COMPANY OUGHT TO BE FLOATED WITH MODERN APPLIANCES—A PENNILESS CARPENTER TURNED OUT A RICH MAN FROM THE BOWITIYATENNA GEM PITS—ILLEGAL GEMMING ON CROWN LANDS—GEM STRATA TO BE FOUND AT CERTAIN PLACES IN SABARAGAMUWA—THE NATIVES GEM THEIR OWN LANDS—A COMPANY OUGHT TO BE STARTED BY MESSRS. SYMONS AND SHAND FOR GEMMING ON EVERTON AND RANGWELLETENNE—WELL WORTH A COMPANY WORKING WITH DREDGERS IN THE KELANIGANGA AND KALUGANGA—REFUSAL OF ALLEGED OFFERS TO GOVERNMENT BY THE ROTHSCHILDS AND OTHERS.

Sabaragamuwa, 22nd June 1889.

When on a recent visit to Rakwana I was astonished at the extensive gemming which is carried on by natives, and agreeably surprised to see the enterprise exhibited by some of the miners who have systematically carried on operations for years past. As you have been publishing a good deal about gemming lately my observations during an hour's visit to the mines at Bowitiatenna may not be without interest.

A walk of four miles from the town of Rakwana by the Kukul Korale bridle road brought us to the top of Everton Gap, where the land (abandoned coffee) was perfectly riddled by gempits, both on Everton estate on the one side and Bowitiatenna on the other. Owing to the gentleman who was looking after the proprietor's interests on the former (Everton) property, having left the district and no one being authorized to receive the rent from the gemmers, all operations have been suspended, leaving the remains of a small village of tumble-down kadjan butts, &c. On the latter, however, a scene of life, happiness, prosperity, and plenty of the good things of this life

presents itself. Scattered about over an area of about 50 acres of abandoned coffee there must be at least one thousand miners at work, mostly of Sinhalese and Moorish castes, fine, muscular, robust-looking fellows who by repute are the worst characters the Western Province can produce. There is a good thatched shed erected over the mouth of each shaft, which looked like a dwelling-house till we got inside, where we found a shaft 16 fathoms—96 feet—deep, regularly built all the way to the bottom with a framework of jungle wall-plating which supported a lining of 18 by 1 in. planking all round the sides which measured at the top 12 by 6 feet narrowing towards the bottom. There is also a line of beams from the top to the bottom separating the shaft into two squares of 6 by 6 feet each, on both sides of which, set on a strong framework of timber, there is a winch, a plain wooden one with a handle fixed on at each end, with two men working it. A heavy coir rope about 3 inches in diameter was bringing up the water barrel on the one side and sending down an empty one on the other. On the other winch the same performance goes on taking up earth, I could see the water glittering at the bottom, and was quite surprised when told that a man was coming up in the barrel. Sure enough out he popped. I was told that no less than 20 men were in the pit at the time of our visit, and that their work would be over at 6 p.m. when a second relief would go down, making an average daily output on the checkroll of 40 men at a cost of about R600 per month in the one pit. If stone or rock was met with it was blasted out till the present depth was reached. Upon inquiry as to what the 20 men were who were said to be in the pit, were doing, I was informed here and there all over the place, tunneling in different directions, looking for the "illian," which I was informed had just been struck by some of the men of one party. I would not believe this till convinced by the man shouting at the top of the shaft to those below for a reply, which was freely responded to in different directions. It appears the gravel varies in thickness from three to seven feet, and sometimes two gravels are found, the second about 20 or 30 feet below the first, and much richer in precious stones of a far superior quality. "But where is the difficulty in always finding and working the second illian?" I asked, and was told "Water, water, is our enemy." We cannot keep it down when below 120 feet or when we get to the level of the stream,"—pointing to it below. We were then shown a tunnel into the side of the hill below, made for the purpose of allowing a free draught of air into the mine, where work goes on night and day with lamplight. Another contrivance worthy of notice is the spouting for taking down the "illian" to the stream to be washed.

The owner of the land, Dr. Fernando, Mr. C. H. De Soysa's son-in-law, is paid a rental of 1-5th share of the proceeds from the sale of the gems found. This mode of rental is preferred by all natives because it is more profitable than accepting R10 per man per month, as is done on the adjoining property of Everton. Europeans cannot afford the time to look after their share of the gems: at all events the superintendent of Aberfoyle estate, who had plenty to do to look after his tea work, could hardly be expected to do so when he lives about 10 miles away; so I presume Mr. C. E. H. Symons finds it pays him well enough to accept the above rent instead of running the risk of having the gems stolen, and perhaps be charged with causing the death of a good many miners from constipation (!) through their swallowing the gems wholesale, as is usually done when they work for Europeans. So that it is not to be wondered at one or two gentlemen who tried pits got little or nothing of any value. I have heard of several natives who have enriched themselves at the expense of planters in Rakwana. The temptation to steal a good gem is so great, and the devices adopted for the purpose of carrying out the intentions are so well performed, that the native gemmers themselves find it an impossibility to prevent thefts, which are constantly coming to light after the gem has been sold—probably at $\frac{1}{3}$ of its value—and the thief disappeared.

It would not be out of place here to mention the find of a valuable sapphire on Rangwelletenne estate by a cooly woman near the mouth of an old gem-pit. Mr. Carry, the energetic superintendent, hearing of the find, proceeded to the lines forthwith and challenged the old woman to produce the gem to which request, of course a pointblank denial of the find was vouched for in the most emphatic and solemn manner, with an expression of innocence which only an oriental can command. Mr. Carry was too familiar with the native character to be baffled, so he set to work to search, and brought to light one of the most perfect sapphires ever produced, about the size of a walnut, without a single flaw, round, and of a most exquisite blue. The gem was handed over to the landowner, Mr. Shand, who presented Mr. Carry with a handsome santosam, and the cooly woman with R50. The gem is valued at from 400 to 500 rupees, but in my opinion it is worth much more. [It was sold for R500, and the proceeds were devoted to gemming.—Ed.]

Mr. C. Shand's property, Bowitiatenna, and the adjoining one Everton are teeming with wealth, which only wants European interference and capital to disclose. On both properties a stratum of gravel was discovered and profitably worked—at least on Everton—for the past quarter of a century, varying from 1 to 7 feet, which ought to be followed up wherever it goes, and when it is lost (as it sometimes happens) new shafts ought to be sunk, as the natives do, or boring operations resorted to till found. As to its paying a company, there cannot exist a doubt, if the concern is supervised by Europeans, with all the modern appliances for mining. Goodness knows to what depth or how many strata of gem-yielding gravel may be discovered, so that it may well be wondered why European capitalists have never tried gemming in Ceylon.

It is all nonsense about finding the matrix. It is not required. The "illian" is well-known to yield handsome profits if followed. Even by the primitive and laborious method carried on by natives without any machinery, they, at least those who have had the perseverance to follow up gemming, have all made fortunes, attained a good position by their wealth, and much landed property, instances of which I shall give by-and-by.

Meantime I shall just mention the owner of the two pits we visited at Bowitiatenna named Andris Silva alias Tambi Sinho, who little more than two years ago was working at his trade as a carpenter, and has now amassed considerable wealth, owns horses and carriages, houses and lands, and tea estates, and is now showing many other visible signs of affluence and prosperity, which is well-known to be the proceeds of the systematic gemming he has carried on for the past two years without intermission. It is also well-known that he was almost penniless two years ago; but can now afford to spend R4,000 to R5,000 to get at the "illian" in two pits, which, by-the-by, has only just been hit in one of them. When asked by me why he risked so much money on the mere chance of striking it, he said: "I am sure to find the gem-yielding gravel somewhere, and when I do I know it will repay all my expenditure and leave a handsome profit." So the man evidently knows what he is about, and his enterprise and pluck ought to be conclusive and positive evidence of "Will it pay?" From inquiring as to whether the matrix had been seen by any of the gemmers, I was answered in the distinct negative; but they said (which has also come under my own observation) that blue, rose-coloured, yellow and red quartz has been often met with, also rocks studded with garnets and other coloured minerals, which are so soft that they are called gems or immature gems by the natives, but do not approach anything like the hardness of a precious stone. Their belief is that no exposed matrix exists in the island, but they say it may be found much below the depth of any existing gem-pit. In support of the non-existence of a matrix they said the natives would have found it, and pointing to the top of some precipitous rocks just above in a piece of Government forest named Hangapangella

they said: "Some hundreds of men have gemmed all over that jungle, and do you think they would not have found it, if it existed?" "No: they said" that jungle has been searched high and low, under the roots of trees till a number of them have fallen down, by the removal of the "illian" and in every stream, under boulders, in small cavities, holes in the rocks, and in fact everywhere, till great damage has been done, necessitating the arrest and prosecution of many, but all attempts to stop it have failed, and unless a watchman is put on by Government or licences granted, illicit gemming will continue on all Crown lands." Anyone who travels up or down the Rakwana road cannot help observing the parties of lowcountry Sinhalese and Moormen going up and down, with their bundles on their backs. If asked "Where are you going or coming from?" the reply is "The gem diggings."

Now all the Sabaragamuwa land does not, as might be imagined, contain the gem strata, but they are to be found at certain places. Many pits have been sunk by men ignorant of what they were about in unproductive places—of course to their loss and disgust. Where gems are to be found there is a peculiarity noticeable about the soil, quite visible on the surface, which does not require a scientific man to see or prospect upon and is recognized by all prospecting natives as a sure sign of success. Anyone would suppose in rich gem-yielding Sabaragamuwa that the native would acquire wealth. But no: he will sally forth on the wettest day to the jungle and commence searching and digging with an alavangu till a few baskets of "illian" have been collected, then wash it out in the streams, proceeds of which he carefully conceals in his loin-cloth and takes to town; or should a Moor merchant be in any near village, off he goes to him and sells it, obtaining enough money to keep him for the time being. So, why should he work, cultivating his paddy field, which lies fallow from year's end to year's end? It is no wonder they are cheeky and independent. The natives gem on their own lands, which are known to contain the "illian," but never more than enough to fill their stomachs, for they have no ambition beyond their daily wants, so that their apathy will always keep them poor. There are exceptions, of course, and those few who have kept on gemming are well-known to be wealthy. It would be worth while to ascertain the number of licences issued to gemmers during the last 5 years, and also the value of precious stones sent through the Post Office to different countries, leaving alone what is sold to passengers at Colombo and Galle, to try and arrive at the approximate value of gems produced in Ceylon and the number of men who have laboured for the same. I can pretty nearly estimate the amount of labour that has been employed on private lands. Of course illicit gemming must be only guessed at.

A company surely ought to be started by Messrs. Symons and Shand for gemming on Everton and Rangwelletenne, where no prospecting is required. They have only got to jump into an old abandoned pit and begin where the natives have been compelled to stop owing to the water becoming master of the position, but for no other reason. It is to be hoped also that some of our rivers—say the Kelani or Kaluganga or both—will see a company at work with dredging to raise the whole of the gravel within their length and breadth, and washing machinery with a sieve-like motion to clear as soon as the S.-W. monsoon rains cease, for it is a recognized fact that those rivers' beds' strata contain purer and more valuable gems than any land in the country. But no licences are issued to natives for gemming in them for various reasons, which would not interfere with a European company, to whom the Government could have no objections to grant the right to gem the whole river from the source to the sea beach. Inquiries have been made for gemming land in Sabaragamuwa for a company, and only very recently one of the members of the Rothschild family offered Government one million pounds sterling for the right to gem all the Crown

lands in this province, which was refused.* So look alive ye speculators and millionaires; the first in the field will doubtless secure the most promising and richest gemming land and water, which I calculate would keep several companies at work for years to come.

The Gem Notary Assena Marikar, who has exhausted his Veralupe pits, near the 55th milepost from Colombo, offered Government R10,000 for the land covered by the road and promised to make a new one for nothing to be able to gem the land under the road. But his offer was refused. Surely this enterprising miner who has been at work for the past quarter of a century knows what is under this 30 yards of road or he wouldn't offer such a handsome price for it. More anon about the Gem Notary. I must close for the present.

MANUFACTURE OF GREEN AND FANCY TEAS.

The following extract from Mr. E. J. Brace's "Essay on Tea Cultivation" cannot fail to be useful at this time to many Ceylon Tea Planters. The essay is now out of print.

We now come to the manufacture of Green Teas. Rich strong green teas have of late been realizing extreme prices in the London market, in many cases averaging more than 3s per lb. all round. As the supply must for some years at any rate be extremely limited, we may safely conclude that these rates will be maintained for some years to come. The chief drawbacks to their manufacture are that they require more labour—closer supervision, and in no case are likely even in small quantities to find purchasers in this country. Their advantage on the other hand is that in dull and nasty weather, when the sunshine fails us for withering our leaf for black tea manufacture, it can at once be manipulated for green tea. The planter will therefore in any case do well to have a sufficient number of green tea pans in his factory; and to have his staff so trained as to be able to turn out equally well either class of tea.

With regard to the setting up of the pans, some lay them in the masonry horizontally: others, at a slight incline. For my own part I prefer to lay them at an angle of about 30°. It is then easier to empty the pans of leaf. To lessen the risk of burning, add leaves here and there, and in the final process of bringing out the colour at a high temperature, the workmen will find tossing the tea easier work for their hands, and in consequence do so more carefully.

As I have before remarked, the leaf intended to be made into green tea is not withered in the sun, in fact the manufacturing process may be commenced directly the leaf is brought into the factory. Previous to commencing manufacture, the pans have, I conclude, been fired up to a moderate heat, but not hot enough to cause the leaf to crackle violently so soon as it touches the pan. One man will be required for every eight or ten men employed in rolling to warm the leaf previous to its manipulation. The quantity of leaf that I usually allow to each pan to be worked off at one time is from twenty to thirty pounds. This amount having been weighed out, the head tea-maker takes up enough leaf to make up a double handful for each of the men rolling, and pans it at a gentle heat for about five minutes, or until it is perfectly warm, soft and flaccid. The mass is then swept out of the pan into a basket, and thrown out from this on to the rolling table. It is immediately taken possession of by the rollers, who set to work at once.

* There appears no doubt or hesitation in the mind of our correspondent about this statement, but we hardly believe it possible. However, it will be easy to settle the matter by a question in Council as soon as the Legislative Council reassembles. As regards search for the "matrix," we submit the probability that whole ranges of gem-bearing hills have been worn down by the effects of the tropical heat and rain, have collapsed in fact, matrix and all, into alluvium. In connection with some of the richest alluvial gold diggings in Australia, all search for a "matrix" was in vain. We suspect that deep digging will reveal more gems than any possible blasting of overground rocks.—
ED.

In rolling green tea a considerably greater amount of pressure may be brought to bear upon the leaf than in the case of leaf for black tea, and the matter of the leaf being a little broken does not signify much so long as it is not really cut to pieces and leaves a fine close twist all round. This can only be done by frequently breaking up the balls during this process. When the leaf has been rolled for from five to ten minutes, each roller should take his allowance up off the table and compress it into a ball between his two hands, squeezing as much juice as he possibly can out of it. When this has been done, the leaf should be broken up thoroughly and spread out very thin on a table or mat. The latter point is of the greatest importance, as any slight heating of the leaf would cause fermentation to commence, and a dark colour would be communicated to the liquor after infusion.

So soon as the first batch of leaf has received one roll, a second is brought from the pan, and the process repeated until the whole amount of twenty or thirty pounds has been similarly treated. The whole is then fired up again for from ten to fifteen minutes and then brought back again to receive a second roll. This should occupy about four or five minutes, and the leaf should then be again compressed between the hands and any remaining juice freely expressed. If, however, the first roll has been properly conducted, little or no juice will be seen to exude from the balls. The latter are then broken up again, returned to the pans and the final drying off commences. The temperature of the pans may now be raised considerably, but not to any excessive heat, until nearly all the juice contained in the leaf has been evaporated, and the latter has assumed a greyish black colour. The leaf will turn very dark as it dries, but the colour will be brought out all right afterwards. When the leaf seems fairly dry and assuming a greyish tint, the pan should be made as hot as the workman's hand can bear it. Two men should now be set to each pan, and the leaf whirled round and round as rapidly as possible, not a single particle being allowed to remain stationary at the bottom of the pan for a second, or burning will result. It is on this final process that the "colour" depends, and until the men have become expert at it, and their hands hardened, it is very difficult to get them, without direct supervision, to raise the pans to the proper temperature. The men should relieve one another every half minute or so, until bloom has come out, which may be ascertained by picking a handful out of the mass and holding it up to the light. As the tea cools the bloom will be more strongly developed.

The colour to aim at is a bright, pearly French grey; and if the planter has never seen a really first-class green tea turned out, he should procure a sample from a broker, and keep it carefully as a guide. When removed from the pans the tea may be partially cooled, and then thrown into an air-tight bin. It is of far more importance to keep green tea free from dam than with black; it will absorb the slightest quantity of moisture, and the bloom will be lost, probably beyond all hope of recovery, by another firing. The planter should therefore ascertain carefully that the linings of his bins are free from holes and cracks, and that the lids fit close: otherwise green tea cannot be kept safely for any length of time.

The time taken in turning out a batch of green tea will occupy from two to three hours. I have done in the former time, but then I superintended the work myself the whole time. When the manufacture is left to one's subordinates, it is better to allow a little more time and run less risk of the tea being spoiled. An even, steady heat up to the time of commencing to bring out the colour is the great point to aim at. If you hear your half-dried leaf hissing and crackling all over, have it out into a cooler pan at once.

The tasting of green tea is conducted in precisely the same manner as that of black, but very different results are looked for. The liquor should be a pale primrose straw colour, and the flavour full, strong, and very pungent. The outturn of the leaf should be a bright pea-green. If the liquor be at all dark

we may rest assured that some leaves have been allowed to take colour in the rolling or drying process; and the colour of the outturn will tell the tale by showing a few discoloured leaves here and there. The finer leaf will invariably be found stronger than the coarser, and the flavour of the former will be far superior. I cannot say from my own experience that the tasting of green tea is a pleasant task: it takes one a long time to get over the bitter acrid flavour they possess, and many will never get to like it. However, when green teas have to be made for the home market they must be tasted every day in order to ensure the evenness of quality of the whole break. The increase in price which they command and the facility with which they may be turned out even in the worst weather must serve to reconcile the planter to their unpleasant flavour.

I now have to make a few brief remarks on Fancy Teas. The first that I shall deal with is what used to be classed at Genuine Flowery Pekoe. This consists, exclusively, of the tender, convolute bud at the end of the shoot, picked by itself. It is withered slightly in the sun, but not rolled, and dried off gradually, rather, weather permitting, by sun, than by fire heat. To command the highest price, it should be scented; and then has realized, and may again realize, from 10s to 15s per lb. If, however, the planter takes into consideration the immense cost of picking these fine buds separately, the extreme care required throughout, the whole cost of manufacture, the trouble of setting, packing in small boxes, the loss to his other teas by the absence of the fine Pekoe tips, and the very uncertain state of the market for such a purely fancy article, he will take my advice and leave it alone.

A more useful fancy tea is where the bud, first leaf, and, when tender, the second leaf, also, are picked together and so manufactured. This leaf is then slightly and carefully withered, lightly rolled, but the utmost care taken to secure an even, close twist and curl. It is not fermented beyond such partial colouring as it may require in the trays, and is dried off at a rather less heat than ordinary black tea. The great object is to bring out the Pekoe tips as near an approach to white as possible. It will then class as Finest Flowery Pekoe, and, if well scented, will realize from 4s to 6s per lb. This tea too should be sent home in small boxes containing from 18 to 20 lb. each. It is really a compromise between a black and a green tea, and scenting is almost a necessity in order to command a high price. It would not find a market in this country, and from the trouble attendant on its manufacture is hardly worthy of much attention at the planter's hands.

GARNETS have gone up so much in the market lately owing to failure or exhaustion of the mines hitherto yielding this gem, that experts are being sent to report on all localities which are said to be garnetiferous. Mysore is known to produce garnets in abundance, but whether the gems are of any worth has not been ascertained. Mr. A. Streeter visits Sucklaspoore, in the Hassan district, shortly to report on the garnets of that locality.—*Indian Agriculturist*.

CENTRAL TEA FACTORIES.—A London tea firm makes the following inquiry and suggestion to a Colombo house:—

"We suppose interests are too conflicting to allow of an arrangement by which 10 or 15 contiguous estates should erect one common factory, with a machine capable of bulking 10,000 lb. at one operation. Pool the produce of the estates and divide the proceeds of account sales in proportion to quantity of green leaf sent in. This would give us large bulks of 100 to 200 half-chests to deal with. Now that the whole island averages 9d there is more possibility of combination than before. Messrs. Rucker & Benckraft suggested this in their circular of December 3rd, 1885, and we suppose that since then 50 factories have been erected where 10 would have sufficed and saved vast outlay."

HIGHEST CINCHONA ANALYSES: JAVA AND CEYLON.—We mentioned the other day that crown chips from Alnwick estate had analysed in large quantity up to 6.73 and renewed crown shavings to 7.40 per cent sulphate of quinine. In contrast with this, it may be well to mention that the highest analysis of Java estate bark in 1888—doubtless Ledger bark—was 9.42 per cent of quinine sulphate.

TOBACCO.—We learn that Mr. Dickson's London Company is not likely to go in for cultivation, but for the establishment of depôts dotted all over the country where the green leaf can be bought up and despatched, we suppose, to the central curing establishment in Colombo. The price to be given for the green leaf is stated to be 25 cents per lb. Meantime, Mr. Vollar is reported to be opening for tobacco near Katugastota, on account, no doubt, of the local Company.

SALT AS FERTILIZER FOR GRASS.—Grass in our climate is much injured by droughts, and salt is one of the best absorbents of moisture. A dressing applied in Spring to grass land will help to keep it cool and moist through the growing season, and benefit thus if in no other way. But salt is also a solvent, and enables grass roots to avail themselves of soil fertility, that without it would be locked up and out of reach. By developing other mineral fertility a dressing of salt will make herbage grown by its aid more palatable and nutritious. If it can be evenly distributed, as it can be by sifting out small lumps, and putting on with a drill, 150 to 200 pounds per acre will be none too much. The common practice is to sow some salt with the grain crop with which grass seed is sown. On an old meadow the drill may be loaded with salt, and its teeth allowed to scratch the surface as the salt is distributed, thus doing two jobs at one operation.—*American Cultivator*.

SILK INDUSTRY OF GREECE.—After having experienced a period of great prosperity, the silk industry in Greece, says the *Journal de la Chambre de Commerce de Constantinople*, is now in a depressed condition. The production of cocoons, which in 1855 amounted to between 1,200,000 and 1,400,000 kilogrammes, fell in the period comprised between 1870 and 1880 to about 500,000 kilogrammes. Since the year 1884, this quantity has still further decreased, and the production, which is centred in the south of the Peloponnesus, in Messenia and Laconia, did not exceed 200,000 kilogrammes of cocoons, that is to say a yield in silk of about 18,000 kilogrammes, of which about 10,000 kilogrammes are exported. This diminution must be attributed to the disease of the silkworms and to the low price of cocoons. Almost all the cocoons and silks from Greece are shipped to Marseilles, and Calamata is the principal port for shipment.—*Journal of the Society of Arts*.

OIL OF SASSAFRAS.—The manufacture of the oil of sassafras is becoming an important industry in some parts of the American, especially in the Southern States, where this tree is common. Only the roots are used; they are chopped up into small pieces by a machine constructed for the purpose, the oil being then distilled from the chips by the aid of steam. About one gallon of the oil, weighing nine pounds, is obtained from one thousand pounds of the chips. The uses for which the oil of sassafras can be employed are numerous and varied. It is a favourite perfume for soaps and candies; it is used as a solvent for different gums, and as a liniment. It is also very largely employed in the manufacture of several popular proprietary medicines. The importance of this industry may be expected to increase rather than diminish, as the sassafras and the persimmon are the two trees which are spreading most rapidly over the old and abandoned fields throughout the Southern States outside of the pine belt proper; and, at present prices, good wages can be made digging out the roots.—*Garden*.

TIMBER DISEASES.—At the Royal Society *conversazione*, held on May 8, among the curiosities exhibited, were, says *Nature*, various parasitic fungi, by Prof. H. Marshall Ward. These specimens included: piece of deal with grey mycelium of *Merulius lacrymans*, causing the common "dry rot" of timber; and a similar piece of timber attacked by the white mycelium of *Polyporus vaporarius*, another and quite different fungus, which produces a form of "dry rot;" portion of Pine-stem infected with *Peridermium pini*, the *Æcidium* form of *Coleosporium senecionis*—the other form of this parasite is found on various species of Groundsel (it does much damage to the Pines in some forests, producing so-called "cankers" as disastrous as those of the "Larch disease"); specimen of Wheat infested by *Usilago carbo* (*U. segetum*), showing the destruction of the ears by the fungus, the black spores of which completely occupy the interior of the grain; specimen of grass attacked by *Epichloe typhina*, a destructive ascomycetous fungus which infests the flowering shoots of pasture grasses; culture specimens of *Sclerotia* developed from species of *Botrytis*, which destroy certain garden plants. Microscopic preparations of these were also exhibited.—*Gardeners' Chronicle*.

DYES IN "KEW BULLETIN."—The May number contains an account of the yellow-flowered *Delphinium Zaili*, the flowers of which are used for dyeing silk, and which has already been noted in these columns. A report on Tasmanian timber follows, showing that many of them have great value for constructional purposes. Among food curiosities may be mentioned Lily flowers; no smaller quantity than 7,000,000 lb. are exported from Ohio Kiang. The species employed are *Lilium bulbiferum* and *Hemerocallis graminea*, the dried flowers of which are employed for flavouring soup. The bulbs of *Lilium cordifolium* are also used for the starch that they contain. P'u-eh Tea, used in Yun Nan, South-west China, consists of the leaves of a shrub which cannot, for want of adequate material, be accurately identified, but which is supposed to be the Assam Tea plant. The Yam Bean (*Pachyrhizus angulatus*), a Central American leguminous plant, is valuable for its edible pods, which form a good substitute for French Beans, and whose tuberous roots are also edible, and furnish starch. Lastly, a complete list of British and Colonial gardens, with the names of their officers, is given. The Edinburgh Botanic Garden is something more than a University garden, while we are afraid Glasgow is, or was till recently, something less.—*Gardeners' Chronicle*.

MADRAS TOBACCO.—Madras tobacco has already become well established in many parts of India. A very large quantity is annually exported to Burma, whence it is returned to India under the name of Burma cheroots, the wrappers alone consisting of Burma tobacco. To encourage the growth of the best sorts, the Madras Agri-Horticultural Society have for some years been in the habit of giving two silver medals annually for the best specimens of Dindigul and Lunka tobacco, but it has now been determined to increase the number of such medals to four. These are to be given for the best cured Dindigul and Lunka tobacco, for the best cheroots and for the best pipe tobacco respectively. Each exhibit of tobacco is to contain not less than ten pounds of leaf, and each exhibit of cheroots is to consist of one hundred of five different shapes, or five hundred in all, and the exhibitor of cheroots is to state the price at which he is prepared to sell ten thousand of each shape. Each exhibit of tobacco is to be of not less than twenty pounds ready for smoking. Considering the great quantity of tobacco which is grown in Bengal, and of which also large exports are made to Burma, it might be worth the consideration of our Agri-Horticultural Society whether they should not follow the example of the sister society and offer medals for the encouragement of the growth and manufacture of tobacco in this province.—*Englishman*.

FORESTS OF CENTRAL AFRICA.— . . . From about 3° N. to about 4° S., and between the Upper Congo

on the west and the lakes on the east, we have, says *Nature*, in commenting upon Mr. Stanley's recent wonderful journey, virtually a great blank. It is the northern part of this blank which Mr. Stanley has enabled us to fill in. . . . One thing is clear, the expedition passed through the northern section of what is probably the greatest forest region in Africa, extending from about 3° N. to 4° S., and from about 23° to 30° E. . . . The route, he tells us, was covered with creepers varying from $\frac{1}{2}$ inch to 15 inches in thickness, swinging across the path in bowlines or loops, sometimes matted and twisted together; also with a low, dense brush occupying the sites of old clearings which had to be carved through before a passage was possible. Where the clearings had been abandoned for some years was found a young forest, the spaces between the trees choked with climbing plants and vegetable creepers. This had to be tunneled through before an inch of progress could be made. Mr. Stanley's description of the character and extent of this forest in his letter to Mr. Bruce is quite worth quoting:—"Take a thick Scottish copse, dripping with rain; imagine this copse to be a mere undergrowth, nourished under the impenetrable shade of ancient trees, ranging from 100 to 180 feet high; Briers and Thorns abundant; lazy creeks meandering through the depths of the jungle, and sometimes a deep affluent of a great river. Imagine this forest and jungle in all stages of decay and growth—old trees falling, leaning perilously over, fallen prostrate; ants and insects of all kinds, sizes, and colours murmuring around, monkeys and chimpanzees above, queer noises of birds and animals, crashes in the jungle as troops of elephants rush away; dwarfs with poisoned arrows securely hidden behind some buttress or in some dark recess; strong brown-bodied aborigines with terribly sharp spears, standing poised, still as dead stumps; rain pattering down on you every other day in the year; an impure atmosphere, with its dread consequences, fever and dysentery; gloom throughout the day, and darkness almost palpable throughout the night; and then if you will imagine such a forest extending the entire distance from Plymouth to Peterhead, you will have a fair idea of some of the inconveniences endured by us from June 28 to December 5, 1887, and from June 1, 1888, to the present date, to continue again from the present date till about December 10, 1888, when I hope then to say a last farewell to the Congo forest! . . . The mornings generally were stern and sombre, the sky covered with lowering and heavy clouds; at other times thick mist buried everything, clearing off about 9 A. M., sometimes not till 11 A. M. Nothing stirs then; insect life is still asleep, the forest is still as death, the dark river, darkened by lofty walls of thick forest and vegetation, is silent as a grave; our heart-throbs seem almost clamorous, and our inmost thoughts loud. If no rain follows this darkness, the sun appears from behind the cloudy masses, the mist disappears, life awakens up before its brilliancy. Butterflies skurry through the air, a solitary ibis croaks an alarm, a diver flies across the stream, the forest is full of a strange murmur, and somewhere up-river booms the alarum drum. The quick-sighted natives have seen us, voices vociferate challenges, there is a flash of spears, and hostile passions are aroused! . . . Another fact of great interest Mr. Stanley refers to—the existence of a snowy mountain which may rival Kilimanjaro (19,000 feet), in the neighbourhood of Mount Gambaragara, or Gordon Bennett, between Albert Nyanza and Muta Nzige. This may be Mount Gordon Bennett itself, but Mr. Stanley does not think so, and he is supported by the few data which he furnishes. . . . The abruptness with which the forest comes to an end and the rich grass lands begin, about eighty miles from Albert Nyanza, is another point deserving special attention, and can only be explained when we have accurate observations of the rainfall and other conditions that go to form climate. [We most earnestly hope that good collections of plants have been made by the expedition, for there must be much that is novel and interesting in the forests so graphically described by Mr. Stanley.]—*Gardeners' Chronicle*.

Correspondence.

To the Editor.

CEYLON TEA IN AMERICA, MR. MCCOMBIE
MURRAY ON.

Philadelphia, 25th May 1889.

DEAR SIR,—I see by the *Observer* that planters are slow to take up shares in the new Company. It seems to me inconceivable that such can be the case when so much is involved. I do not purpose remaining in the field as a public advocate any more; the planters having an able representative in Mr. Pineo, who will shortly fill my place in this respect; but I would just say that the sooner the planters make a name for Ceylon tea in America the better for them. The value of Ceylon tea for years to come will depend upon the amount of advertising done on its behalf. The biggest men in the tea line in this city all say the same about Ceylon tea. It must be sold cheap—that is at a *sacrifice*—to get it into the market, or a demand must be made by advertising to make a value for it to the dealer. I have now changed once more for the better, and am doing business in one of the best equipped stores in the city (half share in a new and entire building) supplied with every convenience for making tea and coffee, ladies' retiring room, &c. &c. We have our own coffee roaster and machinery and hope to do good business in the future. I expect Mr. R. B. Arthur from New York to see me every day. He has a beautiful store in New York city, fitted up in the Oriental style, and, like the man himself, in a very substantial way. He means business, and will succeed in the end, although he finds already that it means war to the knife. I had much pleasure in spending a day with him a week ago, and look forward to a visit from him next week. My Denver man is doing well and deserves more support than I can give him, but I have said my say on all such subjects. I have to thank you for the courtesy you have always shown me in placing your columns at my disposal, and I only hope that my views as expressed, from time to time, will prove helpful to those who are about to enter the field in the cause of the Ceylon Tea Enterprise in America. For my own part, I will fight the fight which is set before me in my own small way, and if my present step proves too ambitious for my means, which is not impossible, I will at least die hard in fighting for the best interests of Ceylon generally, and my late fellow-planters in particular.

In retiring from my self-imposed duties as correspondent in favour of one whose interests and connection with the planters is now more immediate, I wish every success to the new and all-important undertaking, and would give but one last word of advice to the planters in closing, viz., Consider well what you decide to do; but, having decided, *work unanimously*.
J. MCCOMBIE MURRAY.

TOBACCO: JAFFNA GROWN.

Uduvil, 21st June 1889.

SIR,—I send for your inspection samples of tobacco recently raised in Jaffna from seed obtained from Deli on the eastern coast of Sumatra. This variety is so peculiar to this locality and obtains such high favour in the European markets, the dissemination of the seed is prevented and guarded against by planters with the utmost jealousy. For flavour and odour of no other variety is said to equal it, and the cultivation yields very profitable results in Sumatra, notwithstanding the ex-

cessive cost of labour and necessity of allowing the land to lie fallow for four years after each crop. With the object of testing the suitability of Jaffna soil for it, a small quantity of the Deli seed was procured with great difficulty, and cultivated in a plot at Uduvil in Jaffna. The land selected was not rich, but richly manured with farmyard manure. These were planted in a lot with the ordinary Jaffna variety and thrived well. The leaves were of a larger size than those in Deli, but, compared with the Jaffna tobacco, were much smaller. The height of the plants averaged seven and a half feet with about 12 leaves each, while the native variety yielded only about 7 or 8. The shortness of the leaves allows 1,500 plants to stand in an area occupied by 1,000 of the Jaffna variety. In curing I have followed as much as possible the method I observed at Deli, but owing to the shortness of the crop and the want of special appliances, the process was not entirely successful. One obstacle in the way of securing fine aroma is the want of summer rains which would have washed away certain bitter principles exuded by the leaves.

On submitting to local experts the tobacco was pronounced as finer than the local kind, but the great point to be ascertained is as to whether the variety as produced locally would suit European tastes and suitable for export. If this be favourably reported on, there is a great future for the only paying agricultural industry in Jaffna—that of tobacco culture—which is becoming depressed owing to cheap production in India and elsewhere. Any information as to the quality of these samples and their probable values and direction for curing will be of great benefit.—I am, sir, your obedient servant,
A. CANAGASABHA PILLAI.

[We referred the sample to experts in Colombo; and in returning it they say they have examined the new product with much interest. "The size and shape of the leaf," they say, "are very good. Texture too leathery for fine tobacco fit for export. It is also too weak, i.e., not elastic enough, due no doubt to faulty preparation. Color abominable, unfit for any purpose except filling, cause probably insufficient and (or) faulty system of drying. On fermentation there is not a trace, the quantity being probably too small to bring it on. But for the absence of this latter and the very bad color the tobacco might have been fit for export but would have fetched but a poor price owing to its inferior texture and the fact that it has been manured which gives bad burning quality." The sample may be seen at this office.—ED.]

PADDY (RICE) GROWING IN CEYLON:

MR. ELLIOTT'S EXPERIMENTS AT GALLE AND BATTICALOA:
ANSWERS TO CRITICISM.

Batticaloa, 25th June 1889.

DEAR SIR,—My statement of expenditure included all the outlay entailed including the necessary amount of *watching*.

Mr. LeMesurier's estimate of the cost of *watching* is a perfectly *theoretical* one and shows that want of knowledge of the practical cultivation of paddy which has led to such misconceptions. No paddy field in Ceylon has a *separate watcher* to whom any special allowance is made for this duty; and in Galle and most of the Southern Province, the fields are not specially "*watched*." They are ploughed, sown, and the cultivators go about other occupations. Some go coal trading to Galle and even farther, arranging for some female "people of the family" or neighbour to keep an eye on the crop and turn the water on and off. They return at harvest time, when the crop is ready to cut. Even

then there is no watching. The threshing is done at leisure, and those engaged in this operation, who frequently work at night, guard and remove the paddy; so here again there is no charge for watching. In Batticaloa, as explained in my paper on rice cultivation,

In Oct. and Nov. the field servants complete the fences and repair the ridges, &c.; and ordinarily for three months after this they have but little to do, beyond sleeping at night in the watch-huts, though they are supposed at intervals to patrol the fences. Their days are practically free, and they can engage, if so inclined, in other occupations, which will not take them too far away. As a fact, all grow plots of vegetables and tobacco on the higher portions which are to be found in every Munmar land, besides shooting game, fishing and collecting jungle products. In some localities they are able in January to undertake the cultivation of lands for Kalawellamai, especially in the southern districts. In March the reaping begins and the crop might be all threshed out by the end of April, but in practice it is stacked and threshed out later at leisure, to admit of the field servants taking part in the cultivation for Kalawellamai now going on.

Consequently in Galle the experimental field was not watched and no charge was incurred on this account. In the Batticaloa case, until the fence was completed and the crop came above ground, no watching was done. After that a man was engaged to sleep in a watch-hut, for a period of two months to watch the field and the experimental garden in the neighbourhood. For doing this he was paid one ammunam of paddy worth R7-50, half of which was debited to the paddy experiment and half to the garden. By day this man's services were not required and he went and obtained work elsewhere. This is in accordance with the custom of the country, where a substitute is at times hired when the regular cultivator cannot himself sleep at his field. At the end of the three months, the tract having been sown with 90 days' paddy, the crop was ready for reaping, when some of the reapers lived on the land and no separate watcher was required or employed.

Under these circumstances the watching at Batticaloa cost 3-75, and this was included in the item for fencing, R5-60. Lest anyone should cavil at the small balance for fencing, I had perhaps better add that the share of the general fence of the tract comes to 12 fathoms, for of course the 7 acres was not separately fenced.

The fact is that as the country is getting settled the necessity for both fencing and watching is disappearing. In a large portion of Galle and Matara there is neither one nor the other, and it is coming to this here.

If a large extent was cultivated by one proprietor on the cash system, it would be unnecessary to go to any large expense for watching, as a certain proportion of the labour force (for whom employment all the year round could be arranged) would reside on the property in suitably placed lines, just as is done on a coffee or tea estate. Possibly one regular paid night watcher would be wanted for 100 acres (chiefly to guard against the incursions of the pigs), whose services in Batticaloa could be readily obtained for 25 cents a night—say for 180 nights = R46—say 50 cents an acre.—Yours faithfully,
E. ELLIOTT.

P. S.—Paddy selling today for export to Jaffna at R8 to R8-25 per ammunam of 7½ bushels = R1-10 per bushel.

THE FUTURE OF CINNAMON : THE NEED OF STOPPING THE EXPORT OF CHIPS.

Golua Pokuna, Negombo, 27th June 1889.

DEAR SIR,—The persistently low prices realized for cinnamon bark during the past 7 or 8 years,

and the serious outlook in the future from the fact that the exports instead of diminishing are increasing, has caused me to address some of the largest owners of cinnamon property with a view to inducing them to discontinue the preparation and sale of "chips," which, in the opinion of most growers, is the main cause of the continuance of low prices. This of course is no new revelation, for we have it on record that at the inauguration of the "Ceylon Agricultural Association" held in Colombo on the 24th June 1882, this question was the very first discussed; and the following resolution was proposed and adopted by that large and influential meeting:—"That the Committee appointed today do take into consideration the question of the large exportation of chips that is now being made and which this meeting believes has materially contributed to a fall in prices of cinnamon, and report on this subject to a general meeting of this Association on a day hereafter to be named &c." The Committee presented their report on the 1st August, the pith of which was contained in the following clause. "The Committee under these circumstances trust that all members of this Association who are interested in the cultivation of cinnamon will join in doing their utmost to stop the scraping of chips say for a period of three years, save for the purposes of their own stalls and those of their constituents." (For fuller information see pp. 129 and 238 of vol. II. of the *Tropical Agriculturist*.)

With the adoption of the resolution and the recommendation of the Committee, the matter, so far as I can learn from inquiries, ended; and the position today is much worse than it was in 1882. The output of both quill bark and chips is greater, and prices have receded till they leave hardly any visible margin for profit. That one attempt has failed is no reason that another should; and I think the time has arrived when a fresh, more determined and more united effort should be made. The replies to my letters are sufficiently encouraging to warrant a meeting being called to discuss this question and to endeavour to, if possible, arrive at some satisfactory solution of the difficulty. Before however calling a meeting it has occurred to me that perhaps it would be well to have the subject thoroughly ventilated through the local papers, both English and Sinhalese, so that when we do meet we may have some well-matured and feasible proposals to bring forward. The subject is evidently beset with many difficulties which accounts for the "Ceylon Agricultural Association" as quietly acquiescing in permitting the matter to drop out of notice. The more light we can get through discussion the better our chances of ultimate success. In endeavouring to revive an interest in this subject I am at trying to effect something more than the mere passing of resolutions which bind no one; and if I thought that the present movement was likely to be as barren of results as was that of the Agricultural Association in 1882, I should have small heart to proceed: I hope for better things however. Proprietors must see that unless they can devise some means by which the price of cinnamon can be raised, the cultivation of it by many must become unprofitable; indeed to some, I fear, this stage has already arrived, for how can it pay the owner of an estate to cultivate when the bulk of his crop sells at from 6d to 8d per lb. in the London market? Any proposal therefore likely to offer a prospect of improving this state of things should, I think, be cordially welcomed and carefully and seriously examined. It is too much to expect that all cinnamon growers will consent to cease to prepare chips; ignorant

people will not see the advantages to be gained. My hope, therefore, is in the large body of intelligent and influential cinnamon proprietors who must represent quite two-thirds of all cinnamon property; these gained success may fairly be considered certain. I will now throw out a few suggestions for consideration and discussion:—

1. To call a meeting of all interested in the cultivation of cinnamon to discuss the question of entirely discontinuing the preparation and exportation of chips.

2. To appoint a Committee with powers to correspond with owners of cinnamon estates of 50 acres and upwards to try and persuade them to join in this movement.

3. To consider the feasibility of forming a Syndicate of all who join in this movement for the purpose of bringing up chips from the small gardens, to be converted into oil.

Suggestions 1 and 2 seeing they bind no one to anything will no doubt be agreed to. In the event of the Committee being successful in securing the assent of the majority of growers, which I sincerely hope they will be, what then? Are we to be content with that? Are we to have no reasonable guarantee that all will act in good faith? I certainly think it is absolutely necessary that we should, otherwise our proceedings will be a farce. I would therefore propose that an agreement should be drawn up and signed by each consenting party binding himself *on honor* not to prepare or export chips for a period to be determined upon. No honest man need take umbrage at being asked to subscribe to a document of this tenor. It would tend I submit to give confidence where confidence is essential, and very few I trust would be found so dead to truth and honor as to break such an agreement. Should we be so fortunate as to reach this stage, we would have great cause for congratulation, yet this would only be a small measure of relief and would not secure the full object we have in view: here then would come in my 3rd suggestion. The annual exports of chips is about 500,000 lb. or quite one-fourth of the total yearly crop of cinnamon. We might, I think, fairly infer that one-half of this would be represented by estates that would agree not to prepare chips, leaving the other half or 250,000 lb. to be dealt with otherwise. I propose therefore that all who agree to refrain from preparing chips do form themselves into a Syndicate for the purpose of buying up *all* the chips that are offered for sale in the local markets, paying a price equivalent to the highest that could be obtained in the London or continental markets so as to insure that none is exported. It is well-known that bark cinnamon oil is greatly adulterated by some manufacturers, if therefore pure oil only were made I feel convinced that all the chips now used for this purpose, as well as the 250,000 lb. mentioned above would all be absorbed, and that without any danger of overstocking the market. Particularly would this be the case if the manufacture of "cinnamon-leaf oil" were suppressed, for of this above from 80 thousand to 100 thousand ounces are exported annually. Proprietors seldom manufacture this oil themselves, and it has often been a puzzle to me to find a reason why they should allow others to prepare it. The amount paid by the owner of a still to the estate for the privilege of being permitted to use as much leaf as he likes is from R50 to 100 a year, and for this paltry sum he allows his land to be robbed of hundreds of tons of leaf that should be returned to the land to enrich it, while he aids and abets in throwing on to the market thousands of ounces of oil which help to keep down the price of his

quill bark: could a more suicidal policy be imagined! This practice is to my mind the height of folly, and instead of encouraging it I would willingly pay several hundred rupees annually to keep off the "leaf oil" distillers from any property I had anything to do with. To sum up, the remedy for low prices is in the hands of growers themselves. Ceylon has a monopoly of cinnamon; and if its output is reduced there need be no fear of any other country stepping into supply the deficiency. Let all proprietors *firmly* refuse to permit the manufacture of "leaf oil" on their estates and then there will be a demand for all the bark oil we possibly can prepare from chips. The Syndicate of growers will most likely make sufficient profit from the manufacture of oil to cover all expenses connected with its working, but should a small loss accrue it would be insignificant when distributed over the acreage that would be represented; while the gain in the value of quill bark by the total suppression of chips would be considerable. Proprietors of cinnamon property hold a unique position, and if only one-half of them will for their own interests be unanimous, they will be able completely to control the cinnamon market. The above few remarks are written in the hope that they will be taken up and fully discussed by those in whose interest they have been formed. It is no exaggeration to say that the subject is one of vital importance to cinnamon proprietors (aye and superintendents too, as their interests are identical) and that they cannot afford any longer to let matters drift as they have hitherto done.—Yours truly,

WILLIAM JARDINE.

FIG TREE SEED.

June 28th, 1889.

DEAR SIR,—As a duty to the public, I think the attention of the advertizers of this seed should be called upon an explanation. What is meant by Fig Tree Seed? If they mean the Ficus family, "Nat. Ord. Urticaceae," we have some 26 varieties indigenous to Ceylon and which can be propagated by cuttings with very little care. On the other hand, to treat with the cultivated forms grown all over the world, horticulturists would rather repudiate the idea of raising plants from seed, when our finest varieties taken from cuttings or layers can be sent by post anywhere. The finest variety of Fig grown in the island was brought from Italy some 25 years ago by an old estate proprietor. In Udapussellawa the true stock is still to be found.—Yours,

ARBORATOR.

[We take it for granted that the seed advertised is that of the cultivated fig, and the question is whether good varieties may not thus be obtained. It might be well if the origin of the seed were stated by the advertisers.—Ed.]

FIG SEED.

DEAR SIR,—As you surmise, the seed we are advertising is of the cultivated fig. We have ordered forward four varieties and on their arrival we shall give you further particulars.—Yours,

W. H. DAVIES & Co.

BONES: BURNT OR GROUND?

29th June 1889.

SIR,—I have a large quantity of bones, and wish to know what is the easiest method of reducing them to powder. Sulphuric acid is too expensive. What would be lost by burning them in a kiln, as we do lime, or in a pit as we do charcoal?

Any information you or any of your numerous readers can afford will be gratefully received and be of value to other planters living near to the towns.—Yours faithfully,
G. F.

[Bone-ash, the result of subjecting bones to combustion, is a useful manure, although it must be certain that a large portion of the ammonia must be lost in the process of burning. The main constituents of the ash are 80 per cent phosphate of lime and 20 per cent made up of carbonate of lime, phosphate of magnesia, soda and chloride of sodium (common salt). If large quantities of bones are used, we know of no better means of getting them broken or ground, coarse or fine, according to wish, than at the mills in Colombo, those of the Commercial Company and others, who prepare the substance for tea and rice culture. If the quantity is small or the distance from the mills great, the bones can be broken up with a hammer, or by having a garden or road roller passed over them. Then made into a conical heap and liquid cattle shed manure poured over them until they heat under cover of gunny cloth or similar material. This process repeated several times will render the bones fit for use. But correspondents may suggest a better way.—Ed.]

THE GEOLOGY AND MINERALOGY OF
CEYLON: A GEOLOGICAL SURVEY
DESIDERATED.

Colombo, 1st July 1889.

SIR,—I read with interest a letter on "Gemming in Ceylon," signed "Sabaragamuwa," in which the geological side of the question is touched upon. The article in *Once a Week* referred to, I have not seen, and therefore am unable to notice the arguments brought forward to support the theory that gems are produced from ordinary rock by means of electricity. There is, however, what a geologist would call positive proof of certain precious stones having been formed by processes of chemical combination and deposition, chemical exchange, and infiltration, while others as surely indicate their origin from igneous agencies—fusion for instance. I have lately quite accidentally seen a large number of stones that would suggest and warrant a search for gems in the locality. On an estate in Jaela I saw a cutting, made into what was plainly an old river-bed, which contained a vast amount of smooth pebbles imbedded in clay that was nearly pure kaolin, and where stones of the sapphire and ruby type were common. On another estate at Ukuwela there was abundant evidence of the existence of garnets (which I afterwards saw specimens of), with jasperous stone in various interesting stages. In the latter place the original rock had been plainly upheaved by plutonic agency, showing here and there a schistose character, and containing a large admixture of iron ore. Now in both these localities the conditions and the evidences required no remote hypothesis to explain the origin of the precious stones found.

The question started as to whether Ceylon too experienced the 'great ice age' is very interesting. While driving from Nuwara Eliya to Hakgala some weeks ago I was remarkably struck with the contour of the hills, which instantly suggested to me—at a time I was seeking no evidence of the fact—that the country must have been at one time subjected to glacial action. The *Roches Matonnées* were more typical than ever I had seen them in countries where the glacial period undoubtedly prevailed.

But in this connection, a question I would wish to ask is—why don't we have a geological survey of the island made?—Yours &c.,
C. D.

CHINA SCENTED TEA.

Colombo, 5th July 1889.

DEAR SIR,—Mr. A. Melville White desired me to send you the enclosed report on the tea referred to by him in the letter which appeared in your columns last night.—Yours faithfully,

F. F. STREET.

Report on Sample of China Scented Tea received from A. Melville White, Esq.

Leaf.—Yellow, and little blackish, very loosely and lightly rolled, of the appearance of a Ceylon congou or low class souchong, containing considerable woody stalk, mixed and scented with dried Mok-Lee blossoms.

Liquor.—Bright, yellow, pungent, good Foochow scented orange pekoe water.

Tea with the rough yellow sun-dried appearance this possesses is unsuitable for any European market that I know of. It is consumed by the Chinese. The liquor, as a scented tea, is extremely good, and had it the neat twisted tippy appearance of the souchong or pekoe exported to England from Foochow it would be worth somewhere about 1s 4d per lb., the cup quality and scented flavor being exceedingly good. The infused leaf is mostly very soft and tender to chew, and it is easy to see that the tea is made from young leaf, though not plucked or sorted according to the Ceylon plans.

The flower used in scenting this tea is a sort of jessamine cultivated, for the purpose, in the neighbourhood of Foochow. The flower left in this tea is always removed by the Chinese in the souchong or pekoes sold to foreigners in Foochow.

The export of scented pekoes and capers from Foochow to foreign markets last season were:—

Europe	1,077,134 lb.
America	33,944 "
Australia and N. Zealand ..	688,321 "
Colombo, 5th July 1889.	F. F. STREET.

RICE-GROWING EXPERIMENTS.—Mr. Elliott furnishes a very interesting and instructive reply to the criticisms which were passed on his recent report by a brother civilian. We see no reason to doubt the accuracy of the original return and statement of cost; but great allowance must be made for the difference between cultivation on a small and on an extended scale, while it must also be borne in mind that the conditions in the Batticaloa, Galle, and Matara districts are far more favourable than in the majority of grain growing districts in Ceylon.

"DAYS OF OLD."—Government Advertisement:—"Whereas it is deemed expedient by the Government to encourage the manufacture of Coconut Oil at Point de Galle, Notice is hereby given—that a Steam-Engine of ten-horse power, the property of the Ceylon Government, will be sold, subject to the following conditions. The engine will be delivered to the purchaser, at the Customs-House of Point de Galle. The Purchaser will be permitted to pay by instalments, as may hereafter be agreed upon. The Purchaser shall engage to set up the engine in the neighbourhood of Point Galle and to manufacture, by means of the engine, not less than 200,000 gallons of Coconut Oil, within five years after it shall be delivered to him. The Engine shall remain the property of the Crown, by way of security, until payment of the price be fully made, and the stipulated quantity of oil manufactured, after which the interest of Government in the concern will cease. For further particulars application may be made to the Deputy Secretary to Government, who will receive tenders until the 15th January next. By His Excellency's Command, (Signed) P. ANSTRUTHER, Dep. Sec. to Govt. Chief Secretary's Office, Colombo, November 18th, 1831."

OOLONG BLACK TEA.—A Kobe (Japan) native paper says:—Mr. Fujii Katsutaro, who stopped a long time in Formosa with the object of thoroughly mastering the making of Oolong black tea, returned home last year, and samples of his manufacture were received the other day in Kobe from Shid-suoka, where he is engaged. Several foreigners pronounce the sample excellent, and it seems, therefore, that the opinion so generally held that black teas cannot be produced in Japan is quite erroneous.

CEYLON TEA IN PERSIA.—Some weeks ago, it will be remembered, the local Manager of the O. B. C. in Colombo received a trial order from Persia, for 20,000 lb. of tea the result of the despatch of a few samples of Ceylon tea to Mr. Duffield, the Agent of the O. B. C. at Teheran. This order was executed in due course, the shipment consisting entirely of flavor Broken Pekoe, we believe. A few days ago Mr. Morrison, the Manager of the O. B. C. in Colombo, received a telegram from Teheran ordering another 100 chests of similar tea, which shows how the first was appreciated. We hope, therefore, that in process of time a large demand may spring up for Ceylon tea in Persia, where tea is drunk very largely, especially in the north. The steamers of the British India Company call regularly at Bushire, and no difficulty in the way of transport exists, except, of course, when the tea arrives at Persia, for roads are unknown in that part of the world, and caravan carriage is naturally very expensive. Still Ceylon ought to be able to lay tea down in Teheran cheaper than any other country.

“THE ECONOMIC USE OF BARKS” is the title of a paper in the *Gardeners' Chronicle* of June 1st, by Mr. P. L. Simmonds, which we are reprinting in full in the *Tropical Agriculturist*. Meantime we may give the following figures to indicate the importance of the trade in Barks. The imports of Bark last year into the United Kingdom were:

“Cinchona Bark	£661,682
Tanning Bark	£147,107
Extracts for Tanning and Dye... ..	£394,774
Cork	£718,111
Cinnamon	£ 44,061
Total	£1,965,835

To these we may add by estimate:

Oak Bark produced at Home	£1,200,000
Larch Bark	£ 200,000
Total	£1,400,000
Grand Total	£3,365,835”

It is not very satisfactory to find that the import of cork exceeded that of cinchona bark last year.

COFFEE AND TEA IN UVA.—We did not notice and resent as it deserved the remark of a correspondent depreciatory of Uva and its railway in a recent issue, and which came with a bad grace from a district with the worst bargain in a railway the Ceylon Government has as yet got. It will be time enough to criticize Uva and its line, when the annual traffic return bears as poor a proportion to working expenses as the Matale railway has done ever since it was opened eight years ago. Meantime here is reassuring news from a gentleman who is as keen a planting critic as any in the country we imagine. Writing on the 3rd instant, he says:—“An estate in Badulla, about 500 acres in extent, has just given a crop of 8,500 bushels of parchment and looks well for next year. Green bug is less prevalent than it was last season. Tea doing well in Badulla and the higher features of Haputale. In the former district a field on patana soil has just given 410 lb. an acre between the 3rd and 4th year!”—We do not quote this, of course, as proof positive that coffee as well as tea are to continue to flourish for ever in Uva; but with its fine soil and climate and the advantages which a railway will bring, we feel sure that profitable cultivation of one kind or other will last there as long as in any part of our planting districts.

PLANTING COFFEE.—We are glad to learn that an experiment in planting a clearing with coffee from Coorg seed is being tried by Mr. Gordon Reeves on Hoolankaude. We hope it may be successful; but are shade trees planted with the coffee as in Coorg and Mysore?

TOBACCO FOR FIJI.—Mr. Alexander Hinz writing in Levuka on 18th May thinks tobacco the very product for Fiji; but he very properly winds up a long letter of two columns in the *Fiji Times*, with:—“Anyone who thinks to grow rich quickly without labour and trouble should certainly leave tobacco cultivation alone.”

VALUABLE DRUGS.—The latest *Perak Gazette* contains a letter from Mr. Ridley, “Director of Straits Gardens and Forests,” dealing with native drugs of value. We have marked it for the *T. A.*, but meantime may quote a remark of Messrs. Thomas Christy & Co. which is recommended as a standard in collecting drugs:—“Anything that is a deadly poison is sure to be of great value, and if you descend from this standpoint you may get other things which are also valuable!”

COARSE FISH CULTURE.—The propagation of coarse fish by artificially hatching their ova has again resulted in success at the Midland Counties Fish Culture Establishment, Malvern Wells, and many millions of young perch, tench, carp, and other fish have been turned out of the hatcheries recently into the rearing ponds, while a considerable number have been distributed in public waters. The American whitefish, introduced into this country by Mr. Burgess through the courtesy of the United States Fish Commissioners, are thriving, and up to the present none have perished. Grants of yearling trout have been lately made to several Devonshire and Midland waters, as well as to those of Surrey and Sussex.—*London Times*, June 10. [The American white fish ought surely to be tried in Ceylon.—Ed.]

THE CEYLON TOBACCO COMPANY OF LONDON have at length, after much searching, found a competent manager for their cigar factory in Colombo, and he will, I understand, be despatched to the care of Messrs. Cumberbatch & Co. by an early steamer. It is found to be more difficult to secure a manager for their tobacco-planting enterprise, and accordingly this portion of their undertaking will be allowed to stand over for the present. In the meantime, they will commence cigar-making at the Ambewatte factory with the best leaf tobacco they can secure on the spot. It will, of course, be a work of time to train hands to the task, but there will be no difficulty in obtaining a sufficiency of work-people amongst the women and children of Colombo, who will be glad to find easy occupation so near to their own homes. This cigar-making and cotton-spinning together should prove of the utmost service to the native community of your capital.—*London Cor.*, local “Times.”

PLANTERS IN SUNGEI UJONG IN 1888.—The Residents' Report shows that good progress has been made with the railway, which is expected to be open for traffic in June 1890, and the trade prospects appear to assure that the line, and any prudent extension of it, will pay well. Building lots, it seems, rose in value more than 300 per cent during the year. Upwards of 8,000 acres of land have been applied for planting purposes, the area under cultivation reaching now 35,871 acres. Planters also have set about extending estates on the coast, owing to a modification of the opium regulations admitting of coolies there getting that drug easily in their own way. And here it may be noted that Messrs. Hill and Katborne raised in 1888, 645 cwt. of clean coffee from 65 acres on their Linsum estate; and on the latter, 61 cwt. of cured cocoa were picked. The estate was extended for growing coffee and pepper so far as labour difficulties admitted. On their Se-Lian estate 45 acres yielded 495 cwt. of clean coffee.—*Straits Times*.

COFFEE DISEASE IN BRAZIL.

The British Secretary of Legation in Rio de Janeiro, in a recent report states that for many years, though with varied intensity, a destructive disease has existed in the best zone of territory for coffee in the province of Rio de Janeiro. It has never been so bad as the coffee-leaf disease in Ceylon and Java, but still has done much harm. A scientific Government employé, Dr. E. Gödde, in correspondence with Dr. Soltmedel, of Java, has now almost proved that the Brazilian root-disease and the Ceylon leaf-disease have the same origin—namely, a small worm in the root, belonging to the group of Nematoids, similar to the worm in beetroots in Europe.—*Rio News.*

THE CINCHONA PLANTATIONS IN JAVA.

The Soekaboemi Agricultural Society is an association of planters in Java which has done a great amount of good work in collecting information and publishing statistics relating to the principal products of the island, notably cinchona, in which its members are interested. By the last mail we received from its secretary a highly valuable statistical table, giving the result of a series of questions which were addressed by the association to all known cinchona planters in the island. The questions include the estimated yield of the crop in kilos., its estimated average percentage of quinine sulphate, and the estimated total yield of sulphate of quinine for the seasons 1888 and 1889, as well as the actual quantity of bark harvested in 1888, its average percentage yield, and its aggregate contents in sulphate of quinine. These questions were submitted to the whole of the Java cinchona planters, numbering 115, if we count the Government gardens as one concern. The response has been quite as good as might have been expected. Of the 115 plantations concerned, only 33 neglected, either on purpose or through apathy, to send any returns at all; while of the remainder, 54 have fully answered the questions submitted, 16 have sent incomplete returns, not caring to venture upon any forecast as regards the coming crop, 5 report their estates as planted with immature trees, having yielded no crop yet, and 7 have abandoned their cinchona cultures and uprooted the trees.

AREA OF PLANTATIONS.

But all the principal estates appear to have answered the inquiries, and the tabulated reply will, therefore, enable us to form as correct an estimate of the coming crop of Java bark as it is possible to obtain under the circumstances. The area under cinchona culture and the number of trees on the plantations are unfortunately not given in the returns, but we find that, according to the latest official information, there were, in 1888, 10,622 bouws, or about 18,843 acres (1 bouw=about $1\frac{1}{2}$ acres) under cinchona culture in Java. The size of the estates differs widely, of course, and the quantities of bark harvested last year in each plantation range from 233,000 lb down to 672 lb. Most of the Java cinchona estates are situated in the western portion of the island—in the so-called "Regencies" of the Preanger and the residency of Batavia—and their outturn virtually forms the bulk of the yield of the island. Roughly speaking, we find that Western Java contains 72 plantations, with an actual yield in bark in 1888, so far as the returns go, of nearly 3,300,000 lb; Central Java has 19 plantations, returning an aggregate yield of about 400,000 lb; and Eastern Java totals up to 24 plantations nominally, with a harvest of about 220,000 lb. The largest yield of bark obtained on any single private plantation in 1888 was collected on the Soekanegara estate, near Tjiandjoer, in the Preanger, where 233,000 lb. were gathered; and the smallest at Djsinga, near Buitenzorg, Batavia, which yielded only 672 lb. It is a remarkable fact that whereas the highest estimate for the 1888 crop on any single plantation was 179,000 lb of bark (on the Soekanegara estate, just mentioned), no less than five estates estimate their yield for 1889 above that figure, the highest—that of the Goenoeng Melati (meaning Jasmine-Mountain) estate, in the Preanger—being 270,000 lb. The

average equivalent of sulphate of quinine obtained from last year's crop varies greatly, the highest return having been obtained on one of the smallest estates in Central Java, where the bark analysed on an average 9.42 per cent. of quinine sulphate. Next to this came two small estates, one in Central and one in Eastern Java, the former with 7, the latter with 6 per cent. quinine sulphate. The Preanger plantations mostly run from 3 to 4 per cent. It should again be noted that not only do the returns reveal the fact that the estimated yield of bark for 1889 is generally considerably in excess of the actual yield of 1888, but the estimated standard of the bark is also much higher. In 1888 the aggregate estimate of those among the private planters who ventured upon the prediction amounted to 1,860,000 lb. with about 7,659 lb of quinine sulphate, while the actual result was a harvest of 3,171,778 lb of bark, containing 122,889 lb. of quinine sulphate, or an average of 4.14 per cent. For 1889 the estimates are: bark harvest, 3,600,000 lb; quinine sulphate yield, 151,250 lb, or say an average of 4.20 per cent. The year 1887 was exceptionally humid in Java, and while the moisture was generally favourable to the young plants and those in the nurseries, it had a bad effect upon the old trees, and consequently upon the yield of bark.

THE GOVERNMENT PLANTATIONS.

As already pointed out, the great mass of the cinchona grown in Java is produced in the province known as the Preanger Regencies, and occupying the south-western portion of the island. This province is of a highly mountainous nature, being traversed by two important chains, on the slopes of which, at an altitude of 5,000 to 6,000 feet, and in a temperature rather too low to be suitable for coffee-growing, the plantations are situated, many of them on the clearings of old mountain forests, which have been freed of the high *alang-alang* grass overgrowing them. The large Government plantations, containing over 1,500,000 trees in the open ground are also found in this province at Tirtasari, Tjiniroean, and Nagrak, near Bandung. They produced in 1887 nearly 800,000 lb of bark; their area is being constantly extended, and the old trees replaced by young ones of richer variety. It is now nearly thirty-five years ago since the first successful attempt at propagating cinchona was made in Java by Dr. J. K. Hasskarl, a German savant who had held the position of Government botanist in the Buitenzorg Garden, and Mr. F. Junghuhn, who had already made a great reputation in Holland and its colonies as a naturalist and scientific investigator. Although the former was the man who actually brought from South America, after a long and perilous journey, the plants from which the present cinchona trees in Java have originated, to Junghuhn belongs the credit of having carried the venture to a successful issue, and of having so carefully managed the plantations that when he relinquished their direction there were no less than 540,000 plants growing in the open, and some 620,000 in hothouses. Exactly twenty-five years ago, on April 24, 1864, this famous naturalist died at Lembang in Java, in the centre of the plantations which he contributed to create. Mr. K. W. van Gorkom, one of the subsequent directors of cultures in the Dutch East Indies, in his valuable book on the cultivation of staple products in Java, relates how Junghuhn's grave is placed at the crossing of the two principal avenues of *succubra* trees in the Lembang plantation, a white needle which has been erected over the burial place being visible at a great distance. In Junghuhn's time two cinchona plantations were also commenced in other parts of Java, viz., Bezoeki in the extreme east, and on the high mountain-plateau of Dieng, in Malang, one of the loveliest districts of the island, but neither appears to have been successful.

PRIVATE PLANTATIONS.

As regards the cinchona estates belonging to private owners, the report which we have quoted makes mention of two cinchona plantations at Lebak, in the residency of Bantam, but only one of these has sent in a

return, and this shows the undertaking not to be of any special importance, the 1888 crop having been only 38,000 lb. Lebak may be mentioned, in passing, as being famous by reason of its connection with one of the most powerful modern Dutch authors, who by his writings, under the pseudonym of Multatuli, did much to improve the lot of the Javanese, among whom he had lived for many years as an official. The first attempt at planting cinchona by a private individual was made in Java in 1886 at Garoet, in the Preanger, a district in which, according to the returns, there are now no less than eleven plantations. This experiment was followed in the same year by the proprietor of Tjomas, one of the best-known estates in Java, and where the cultivation of new articles appears to be always taken up with considerable energy, if we may judge by the fact that one of the consignments of coca-leaves which was recently offered for sale in London was grown on the same estate. Tjomas is in the residency of Buitenzorg, so-called after its capital, which is the residence of the Governor-General of the Dutch East Indies, and of a large number of the well-to-do Batavia traders, who find among its splendid scenery and salubrious climate a pleasanter abode. (Buitenzorg signifies "free from care") than the comparatively low-lying and swampy soil of Batavia can offer. At Buitenzorg is also found the magnificent botanic garden, now under the direction of Dr. Tröub, which has contributed so much to secure the successful propagation of many exotic economic plants in the Dutch Indies. It was in these gardens that tea was first cultivated from plants sent from the Japanese island of Decima in 1826 by Dr. Siebold. Vanilla, cinnamon, and many other products were also propagated from here. At present there are in Buitenzorg seven cinchona plantations, but their output is small. They are all situated in the southern part of the residency, the northern part—and indeed, most of the north coast of the island being unfit for cinchona cultivation by reason of the alluvial character of the soil. The higher mountain ridges are the proper localities for cinchona, coffee, and other produce, and they, as a rule, are nearer to the Indian Ocean, where the coast of the island rises steep and high above the almost unfathomable depth of the sea, than to the shallow Java sea in the north, where the soil is better fitted for growing rice, sugar, tobacco, indigo, and the like. The largest and richest plantations are found in Bandung and Tjiandjoer, the former district containing no less than seventeen and the latter fourteen plantations. The remaining Preanger plantations are found at Soemedang (one), Tasikmelaja (three), and Soekaboemi (five), the latter place being the seat of the Agricultural Society, which was founded, we believe, a few years ago for the purpose of promoting the interests of the Java planters, and enabling them to better combat the competition which they had to meet from other tropical countries. In the adjoining residency of Cheribon two plantations have been commenced, but neither of them has yielded any crop as yet, though it is expected that they will produce an aggregate of about 17,500 lb. of 3 to 4½-per-cent bark this season.

PLANTATIONS IN CENTRAL JAVA.

The plantations in Central Java are nineteen in number; but only three or four are of any great importance, the foremost among these being the Pagilaran estate, which in 1888 yielded nearly 200,000 lb of 6-per-cent bark. This estate, with four others, is situated in the residency of Pekalongan, where is found the famous "valley of death," filled with nitrogenous exhalations for some feet above the surface of the ground, and fatal to animal life. Pekalongan is also known as a sugar-producing district. It has been frequently pointed out in this journal that in the present state of the cinchona market the only salvation for the planter lies in the production of a bark of very high quinine standard, and this is now generally recognised by the Java planters. The two richest plantations in the whole island are found in the Pekalongan residency—one of them, the Karang

Mego estate, having in 1888 yielded a bark averaging 9.42 per cent. of quinine sulphate, while another produced 200,000 lb of 6-per-cent. bark. In the residency adjoining Pekalongan—that of Samarang, the capital of which, of the same name, is the third most important trading-port of the island—there are four plantations, one of which (Langenardjo) produces a very rich bark. The cinchona plantations here, however, are not of much extent, except one at a place called Ambarawa, where the 1888 crop was about 26,500 lb of 5½-per-cent. bark. With one more exception—that of the "My Bagelen" estate at Ledok—all the remaining plantations in Central Java are not as yet of much account. Several of them have sent no returns, some are abandoned, and others are as yet too young to yield any crop. It does not appear as if outside the western part of the island the cultivation, even if in future it should continue to expand, will ever attain that eminence which it has done in the Preanger districts. Cinchona-growing is essentially an Indo-European industry. Some twenty years ago an attempt was made by the Government to popularise the cultivation of cinchona by natives, and thousands of young plants were sent out all over the Archipelago; but the care required in the propagation of the trees is too much for the easy-going Javanese, and they have never taken kindly to the industry. With some slight exception during the earliest years of the Government plantations, cinchona-growing has always been a "free" industry in Java. Other crops have been extended in the island under the so-called "culture system," which compelled the natives to work at fixed daily wages for the Government, to devote a certain part of their land to the cultivation of articles specially indicated by the Government, and then to sell their crops to the Government at a price fixed by the latter. Coffee and tobacco have been made into staple products by these means, while cinchona has been left to the initiative of the European growers.

PLANTATIONS IN EASTERN JAVA.

In Eastern Java which embraces some of the most fruitful and also some of the wildest parts of the colony, there are at present four or five large plantations and several smaller ones, while a few have been abandoned, their cinchona-trees in some cases proving almost valueless, while in others the trees have been uprooted to make way for the more profitable coffee-cultivation. In the Kediri residency there are eight plantations, but not one of them appears important. In Soerabaya, a residency the capital of which is the second largest, if not the largest, trading-port of Java, there are thirteen plantations, most of which are situated on the magnificent highlands of Malang, a plateau which is surrounded, as it were, by a circle of volcanoes, including the Smeroe, the highest mountain of Java, rising some 13,000 feet above sea-level, and the Bromo, an active volcano, which is regarded with superstitious dread by the Javanese as the haunt of the spirit of the Indian Sea, Ratoe Kidool. In these rocks and in their neighbourhood numbers of edible bird's-nests, built by a species of sea-swallow, are gathered by the natives, who sell them to the Chinese, by whom they are regarded as an exceptional delicacy. On the Malang plateau, too, the best coffee is grown, and vast quantities of sugar are also produced in this residency. In the village of Toelian in the adjoining province, near the north coast, is found what is alleged to be the largest tree in Java, a wild kapok-tree (kapok is a kind of vegetable wool, and an important article of trade), the trunk of which measures fifty feet in circumference. In the extreme east of the island, in Bezoeki and Panaroekan, three cinchona plantations are said to exist, but they have either sent no returns or else they are not harvesting at present. The harvest of cinchona in Java generally commences about June or July, when the east or dry monsoon is at its height, and it is mostly garnered by November, when the weather changes and the north-west monsoon, with its storm-laden clouds, breaks over the island from the Chinese Sea, pouring down incessant rains until the following April.

—Chemist and Druggist.

THE CEYLON PEARL FISHERY.—A wrong impression of what our Pearl Fishery has contributed to the general revenue of recent years would be gathered from the bald statement that the average yield was R60,000 per annum. This was the figure given by Mr. Thomas of Madras, but we are not sure of the period for which he reckoned. Possibly he has taken the whole series of years covered by the British Administration from 1796 onwards; but allowance should certainly be made for the fact that from 1838 to 1854 no regular Fishery was held. Taking the period from 1855 to 1889—or 35 years—inclusive, we get an average annual contribution of as near as possible R140,000 even although that includes another blank of ten years—1864 to 1873. These figures give a much more adequate idea of the importance of what must always be regarded as the most satisfactory item in the general revenue of Ceylon.

BOTANICAL STATIONS IN THE WEST INDIES.—The chain of botanical stations in course of formation in the smaller West India islands is being gradually extended. The first to be established was a station at

Grenada. This has since developed into a Botanic Garden, and forms one of the most attractive, as well as one of the most interesting, features of the town of St. George. The botanical station at Dodds, in the island of Barbados, has done most valuable work, chiefly in connection with the experimental cultivation of new varieties of Sugar-canes. Indeed, this station has won the credit of being the first to raise Sugar-canes from seed. A very successful botanical station is in full operation at St. Lucia, where numerous economic plants have been distributed amongst the people. We hear now that the Secretary of State for the Colonies has approved of the establishment of botanic stations at Dominica, Antigua, and St. Kitts and Nevis. These will be worked with such assistance as can be rendered by the Botanical Department at Jamaica, and the indications clearly are that the smaller Island in the West Indies will now be able to avail themselves of both the valuable nurseries of plants, and the knowledge respecting their culture accumulated in Jamaica during many years. By these means also the vast resources of Kew, which is in direct communication with centres like Jamaica, will be made available to remote parts of the empire.—*Gardeners' Chronicle.*

A GEOLOGICAL SURVEY OF CEYLON.

The interesting letter of our correspondent "C. D." (page 116) adds emphasis to the suggestion we have so frequently repeated that the geological formations of Ceylon, some of them curious in a scientific point of view, and others of economic value from the wealth of minerals they bear, should be thoroughly examined and reported on, after the fashion of the Geological Survey which has been carried on now for so many years on the opposite continent of India. Such questions as the existence of comparatively recent plutonic action amidst, and of archaic glacial influence on, our rocks ought to be set at rest. We fear all idea of the discovery of coal must be abandoned, but it is more than probable that a thorough exploration, aided by such appliances as the diamond drill, might reveal the existence of ores, such as those of gold and silver and copper, and of crystals and gems rich and rare, which might add largely to the wealth of the community. Heat, pressure, magnetism (another word for electricity?) may have converted many of the clays and other formations of our lower strata into forms of beauty and value, such as surface evidences have scarcely enabled us to appreciate.

◆

 AGRICULTURAL SHOWS GENERALLY:—AND THE APPROACHING HORSE SHOW IN PARTICULAR.

We take no little credit to ourselves for the revival in the Colony within the past fifteen years of Provincial and District Agricultural Shows. In season and out of season, and especially on the arrival of successive Governors, we pressed on the attention of Government and the Revenue Officers, the advantage to the people of establishing periodical Shows at the capital of each province or large revenue district. The advantage consisted not only in the stimulus to local industry, the incitement to healthy rivalry, and the fostering of a desire to earn honours—in medals and certificates—which are about the most fairly won of any open to the natives of the island; but also in the promotion of social good-feeling among different races and classes and, last but not least, in providing one really innocent and pleasant if not profitable holiday time in the year. To give something again, for the rural Kandyans and lowcountry Sinhalese and Tamils to think and talk about, besides their last and approaching visits to the law courts and temple, would in itself be an indubitable benefit, and in some cases our full anticipation has been more than realized. Suggestions in the press deserve very little credit even if acted on, compared with the credit due to the officers who at much personal trouble, worry, and often expense, have set themselves to get up such Agricultural Shows and Entertainments for their people as we refer to. Notably has this been done more than once or twice with the greatest possible success by that model Assistant Agent, Mr. Baumgartner, in the Matara district; and to some considerable and meritorious extent by Mr. F. H. Price at Kegalla and by Mr. Burrows in Matale. The Provincial Shows at Kandy have not been so much the design or work of one man; but our regret must be that the good example of Kandy has not been followed at other Provincial capitals. An exception must be made in favour of Jaffna and its Government Agent Mr. Twynam. It is time now that Uva was making arrangements for a Show at Badulla, though there may be an inclination to delay until

the railway is finished in order to carry large numbers of visitors on the occasion to the ancient Principality. No such reason can be given for delay at the capital of Sabaragamuwa and of other provinces where no Agri-Horticultural Show has as yet been undertaken.

Meantime, it is difficult to understand the somnolence which has overtaken Colombo and the Western Province for a good many years back in the omission to provide any Agri-Horticultural Show. In days gone by, Colombo always led the way as it ought, in this respect; but there is one indispensable condition of success for such a General Show at the Metropolis, and that is the cordial sympathy and support of the head of the Government. Now rightly or wrongly, of recent years, the provincial administrative officers at the Colombo Kachcheri have been regarded as occupying very much "the cold shade of the Opposition benches," without much encouragement to do aught beyond the absolute duties which each day called from them. This may possibly explain the *hiatus*. We should be very sorry indeed, however, to see the old system of a periodical Agri-Horticultural Show—say once in every two or three years—abolished, and we therefore at the outset, viewed with much suspicion the announcement that the Government Agent or ex-Government Agent and other friends were interesting themselves in any such sectional and fractional affair as a mere "Horse Show." Ceylon is by no means an island distinguished for its stock,—though that may be regarded by some as all the more reason for stimulating improvement in this direction,—nor is it under any circumstances likely to see successful horse-breeding establishments. Throughout Australasia, South Africa and even the old country, Horse Shows may be regarded as gatherings of national concern and interest. Here it is impossible to say that a Horse Show can be a matter of more than sporting and individual interest. We say so much to prevent Mr. Saunders or any other Western Province revenue official running away with the idea that the public can accept the approaching Show as a substitute for the Agri-Horticultural Exhibition long past due in Colombo. On the advent of a new Governor one of the very first duties of the gentleman who may then be administering the Western Province and of his Assistants, should be to make arrangements and to do all in their power to promote a successful and representative Agri-Horticultural Show in the metropolis. This might well come off in the early part of 1891 and we feel sure that all classes of the community would be ready to unite in making it a great success.

Having thus done our duty, in reminding our leading Revenue officers what is expected of them in the early future, we have nothing but good wishes for the minor and sectional, though at the same time in its way, important and interesting Show which was arranged for under such influential auspices at a gathering last week. That the Committee thus appointed have not been idle is shown by the businesslike statement and comprehensive programme published elsewhere. We think the Committee have arrived at a wise decision in treating "subscription" as a guarantee fund to be operated on according to necessity, the hope no doubt being that receipts for admission will cover nearly all the expenditure in getting up the Show, providing medals and other prizes, &c. We think the selection of Slave Island patch for the Show a very good one as on the whole the most central, convenient and generally suitable of all available sites. No doubt it is anticipated that the Show may result in permanent

benefit to the colony by leading to an improvement in the style of horses imported, and by promoting greater care by owners of their animals, in anticipation of periodical competitions. But whether this prove to be the case or not, we are clear that the Show itself ought to be the occasion of an interesting, innocent and instructive gathering, and we hope it will be all the success both in exhibits and attendance, that its most enthusiastic supporters can desire.

THE CEYLON PEARL FISHERY.

Dr. C. Thurston, Superintendent of the Government Museum, Madras, who was recently on special duty in connection with the Pearl Fisheries, has submitted the following report to Government, which is dated 23rd April 1889:—

I have the honor to report that, in accordance with instructions from Government, I left Tuticorin for Colombo on 22nd March, and, on my arrival there, at once placed myself in communication with the Acting Principal Assistant Colonial Secretary, Mr. H. W. Green, from whom I received all possible assistance. It was originally intended that I should travel up to Dutch Bay, from which spot the pearl-fishery was being conducted, by S. S. "Active," on the 26th; but, as she was laden with stores for the pearl camp, there was no available space, and I had to wait for a passage on the small coasting steamer "Prince Alfred," which left Colombo on the evening of the 28th. As we neared Dutch Bay on the following morning the odour of decomposing oysters in the kottu (or kōḍu) was perceptible some distance out at sea, and we saw nine boats at work on the pearl bank. Arrived at Dutch Bay, I found Mr. Twynam, C.M.G., Captain Donnan, and other administrative officers living on board S. S. "Serendib" (marked *Dib* in the accompanying plan), which was moored close to the shore, communication with which was maintained by means of a gangway. Several deaths from cholera occurred on board, including the death of the captain, who had acted as kottu superintendent during the return journey of the "Serendib" to Colombo. The fact that only nine out of the whole fleet of nearly two hundred boats were at work was attributed to the divers being tired and taking a day's rest, and I was not prepared for the sequence of events on the following day. The nine boats were towed into the bay by the "Active" reaching the shore opposite the kottus before 4 p. m. I gathered that the steamer had been of very great service as a tug during the fishery, for, with her assistance, not only were the boats enabled to get to and from the bank in spite of contrary winds, but the diver's work, which is very severe, was considerably lightened by the simple fact that the steamer could bring them back at an early hour on days when, without her assistance, they would have been out at sea until possibly late in the evening and not ready to start off for the bank early on the following morning.

Fortunately, I examined the oysters which were brought in by the nine boats, for, as it turned out, it was the only chance which I had of making an examination. I was at once struck with the fact that the shells of the oyster presented an entirely different appearance to those of the Tholayiram Par (Tuticorin). For, whereas the latter were enveloped in dense masses of algæ (sea weeds) and the surface of the shells covered by variously colored branching and sessile encrusting sponges (notably *Olatiria Indica*), the surface of the shells of the former which was uppermost during life was, in very many cases, covered over and often entirely concealed by delicate stony corals, forming either encrusting masses or branching tufts (*Galaxea Madrepore* &c.), technical details of which it would be out of place to enter into in a non-scientific report such as the present one. Specimens of the shells, with their accompanying corals, many

of which were to be seen lying strewn along the sandy shores of the bay, have been brought to Madras for deposit in the Museum. Further examination of these coral-bearing shells would be of interest, for, as the age of the oysters can be approximately fixed, a very good idea could be obtained by weighing and by observation of the size of the corals on oysters of different ages, as to the rate at which the corals grow—a point on which detailed records of observation are required. Chemical analyses of the sea-water over the Ceylon and Tuticorin pearl-banks, especially with reference to the percentage of lime salts, should also be carried out. Captain Donnan has suggested—and the suggestion is one which is worthy of consideration—that, as my investigation of the Ceylon pearl-banks came to an abrupt termination in the present instance, I should accompany him on his tour of inspection of the banks next October, when he will be accompanied by divers. The middy heat at Dutch Bay was very oppressive, and blue-bottle flies abounded in such enormous numbers as to be a veritable plague, from early morn till sundown. I was told that, in the early days of fishery, the merchants complained of the scarcity of flies, the presence of which is necessary for the production of the rapid decomposition and removal of the animal substance of the oyster, prior to the carrying out of the washing process; but, at the time of my visit, there was no ground for complaint. No such host of flies had infested the camp at Tuticorin up to the date of my final departure from that place (April 5th). The plague of flies at the Ceylon fisheries has occurred on former occasions, for Mr. G. Vane, who conducted the Fisheries from 1855-60, writes as follows:—

"Then come flies, innumerable, of the largest kind; indeed flies are constant plagues, but are worse with a southerly wind, everything being covered with a black mass; a glass of wine or water must be drunk as poured out, or it is filled with flies, but southerly winds do not last long, and it seems as though providentially arranged that the prevailing winds should aid the purposes and needs of a pearl-fishery."

It is much to be regretted that some process cannot be employed, by which the necessity for extracting the pearls by means of the process of decomposition is eliminated. Boiling the oysters, and subsequent search for the pearls in the residues, can be resorted to with advantage by those who purchase on a moderate scale, but would be difficult of application by those who have to deal with large numbers. At Dutch Bay tar was kept burning at different parts of camp, so as to modify the prevailing odour of putridity, and the same might be done with advantage at Tuticorin.

Early on the morning of the day following my arrival at Dutch Bay my suspicion that something was wrong was confirmed by the receipt of information that deaths from cholera had occurred in camp, and that there was a panic among the divers, who, in consequence, had struck work. By 10 a. m. it was decided to abandon the fishery and permission was given for the boats to leave. The divers' quarters and divers' sale kottus were, as a matter of precaution, burned down, and the Government kottu was burned down unintentionally.

By 4 p. m. most of the boats were out at sea, many making for the Madras coast. The fishery being thus finally closed, the object of my visit to the fishery could not be carried out, and I returned to Colombo on the "Prince Alfred" in company with nearly a hundred natives, so as to inform the Superintendent of the Tuticorin Fishery by telegram that many of the boats had started for Pamban and Kilakarai.

The general arrangement of the Dutch Bay camp is shown in the accompanying plan (the distance from the kottus to the divers' quarters being about three quarters of a mile), and it corresponded, in all essential particulars, with the arrangement of the Tuticorin camp. The latter is, in fact, based on what I may term the Ceylon type. As stated by the newspaper correspondent, the camp looked "very much like a military station, for there is a full company of armed police, sentries here and there, flags hoisted, and bugles sounded at the proper time, and guards being

relieved. Go where you will, you will find a police constable on duty. The head-quarters are close to the large water tank. Those on duty in the town can signal to head-quarters at night by lamps."

The Superintendent of the Fishery, Capt. Dobnan, &c., had, as I have mentioned, their quarters on the "Serendib," and various subordinate officers connected with the kutcheri and kottu lived on two native vessels the "Sultan Iskander" and "Antelope" which were moved close to the "Serendib."

A small guard steamer was employed in cruising about the bay, so as to prevent the divers on their return from the bank from dropping bags of oysters in the shallow water, which could afterwards be picked up. This form of fraud—and the frauds perpetrated by pearl-divers are many—was scarcely possible at Tuticorin, where the boats arrived on shore opposite the kottu straight from the open sea.

Good fresh water was obtained from shallow wells dug in the sandy shore, and there was abundance of water, condensed by the "Serendib," in a large tank indicated on the plan, but the condensed water did not seem to be appreciated by the natives.

I had, unfortunately, no opportunity of watching the counting of the oysters in the kottu, or the management of an auction on a large scale; but, so far as I could gather from the counting and sale of the oysters brought in by the nine boats already referred to, the system was the same as that adopted at Tuticorin.

Turning now to a comparison of the Dutch Bay and Tuticorin fisheries, the former had the advantages of—

I. A large fleet of boats (193) and divers.

II. The presence of an efficient steam tug throughout the fishery, by means of which both time and labor were saved.

III. The existence of the oysters in comparatively shallow water and near to land.

IV. The possession in Mr. Twynam and Captain Donnan of two officers with wide experience of the details and possible contingencies of a pearl-fishery.

The Tuticorin fishery labored on the other hand under the disadvantages of—

I. A very small fleet (44) of boats and divers.

II. The absence of a tug for a long time after the commencement of the fishery.

III. The existence of the oysters in deep water and at a long distance from land, and there was, if the health of the camp is left out of the question, no compensatory advantage at Tuticorin.

The total quantity of the Government share of oysters was, therefore, 25,184,015, and the total sum realised as the result of 22 days' fishing, R4,81,887-52. Comparing these results with those of the Tuticorin fishery, the total quantity of the Government share of oysters was 2,398,400 and the total sum realised during the time under notice R55,871-6-5.

A comparison of these two tables is very instructive and brings out very clearly the fact that, whereas at Dutch Bay the fishery was carried on without interruption (no fishery took place either at Dutch Bay or Tuticorin on Sunday the 3rd, 10th, 17th, and 24th,) and, after the first few days, during which time all the boats had not arrived, or were not ready for work, a large and uniform number of boats were at work daily and regularly bringing in good loads of oysters; at Tuticorin on the other hand, not only was there no fishery at all on three days (exclusive of Sundays but on different occasions, out of the entire fleet of 44 boats as few as 2, 3, and 12 boats were at work, with the result that, during 6 out of the 22 working days under review, only 63,400 oysters, yielding R1,781-6-5) fell to the Government share, i.e., the total yield of six days was less than that which was, with one exception, the 19th, obtained as the result of a single day's work.

Lastly.—As regards the work done by the "helmeted divers," I was informed, in answer to inquiries, that they had been tried at former Ceylon fisheries and abolished, and the results of the helmeted divers' recent work at Tuticorin cannot be looked on as either satisfactory or conclusive.

The Ceylon Government will be asked to permit Mr. Thurston to accompany Captain Donnan to the Ceylon banks next October.—*Madras Times*, June 29th.

PADDY (RICE) CULTIVATION IN NORTH CEYLON: JAFFNA THE GREATEST CONTRIBUTOR TO GRAIN REVENUE.

If the amount of grain tax derived by Government is a sure index, as we hold it to be, of the quantity of grain grown in a given district, Jaffna has an indisputable claim to be regarded as the chief rice-growing district of the island. On reference to the statement published by order of the Legislative Council, showing the revenue received as grain tax in the 21 revenue districts of the island for the four years from 1884 to 1887, we see that Jaffna has contributed the most revenue to Government. Ten times the amount of the grain tax represents the money value of the grain that is grown. The following shows what Jaffna and the next best district have each contributed for the four years referred to:—

1884	{ Jaffna	R117,831-60
	{ Uva	117,805-44
1885	{ Jaffna	126,875-33
	{ Matara	84,273-78
1886	{ Jaffna	141,708-96
	{ Kurunegala	109,370-50
1887	{ Jaffna	128,744-82
	{ Matara	84,326-62

The contribution of Uva in 1884 was exceptional for each of the three following years it was under R85,000. Jaffna grows more grain than any other district of the island, not because its area is large, or its soil is rich, not because it has the advantage running water or of irrigation works, but because of that high tillage which seems to be necessary outcome of a comparatively very large number of hands being engaged upon a limited extent of land. There is a general impression that the Jaffna cultivator has a practically sound knowledge of agriculture, and it is perhaps because Mr. Green shares this impression that he has not thought it necessary to make Jaffna one of the centres of the diffusion of agricultural knowledge, in which he takes such lively interest. But it strikes us that the improved methods of cultivation recommended by Mr. Green are more easily followed in a place which suffers from congestion, than in one which complains of, sparseness of population. The general experience is that the narrower the extent, the higher the tillage. The story is told of a Jaffna farmer who, of the 50 lachems of paddy field he originally owned, finally retained only 10 lachems, having given away 40 lachems in equal shares to his four daughters, but who by expending on his small residue all the labour he had originally bestowed on the whole land, was able to raise the same amount of crop. But there is one great, insuperable difficulty in carrying out costly improved methods of cultivation in Jaffna where rain is all the irrigation known in the case of paddy. If it is impracticable to utilize the Puttoor well and to bore artisan wells, it would be useless to introduce costly methods of cultivation. There is however no satisfactory proof given that the two schemes suggested for the irrigation of Jaffna are no easible.—"Ceylon Patriot."

GEMMING IN CEYLON:

ANOTHER VALUABLE STONE FOUND IN SABARAGAMUWA.

(From a Correspondent.)

2nd July 1889.

Five Sinhalese villagers were fortunate enough last week to come across a valuable catseye about the size of an arecanut at Newellepitta, about 10 miles from Rakwana. It is valued at R8,000, but if without flaw it ought to fetch much more. The Moormen are off in numbers to try to buy it.

A large ruby was found at Dewalagama, a few days ago, but owing to some flaws the highest offer is only R250. Rather than sell it at that figure it is to be cut up and then sold. Get the company floated: no fears as to the result.

INSECT PESTS.

It appears from a recently-published report that for years past a destructive disease has been causing havoc, though in varying degree, in the best coffee-growing district in the Brazilian province of Rio. But the insect plague, dire as its effects have been, has been more merciful there than in Ceylon and Java; and in Ceylon, indeed, coffee is losing its pride of place as the chief export in consequence of the competition of tea and cinchona. Investigations lately conducted by competent men of science, both in Brazil and in Java, tend now to give considerable support to the hypothesis that the two complaints—namely, the leaf disease in the great British Indian and Indian Isles and the root disease in Don Pedro's empire—are caused by one and the same thing—that is to say, by a small cocoon belonging to the group of "Nematoids," that devours the root. This worm is also said to be akin to that which destroys the beetroot. To ascertain scientifically the cause of maladies is the first stage towards grappling with them successfully, and hence it may be hoped that before long effectual measures may be taken against the coffee leaf and root diseases, and against that noxious little worm, which seems to deserve a place in the same category with the dreaded Hessian fly, the Colorado beetle, and the phylloxera.—*London Times*.

HOW TO MAKE THE MOST OF A COLONY.

(From *The London Times*, June 8th.)

We shall look for the appearance at no distant date of an interesting volume about the little known British settlement on the Gambia. Its title will, perhaps, be "How I made the most of my Colony," and its author most probably Acting-Administrator Carter. In the June number of that depository of curious lore, the *Kew Bulletin*, there is an account of what he has done in singularly trying circumstances to benefit a languishing colony. Of small extent, the Gambia settlement produces few commodities in much demand elsewhere. Hitherto the ground nut has been the staple product of the country. Exported to Europe, it is there made to yield a useful oil. But it is no longer so saleable as it was. America and Russia produce so much mineral oil that under the stress of this new competitor the sole important industry of the Gambia bids fair to become extinct. In such circumstances most Governors would resign themselves to this condition of things as inevitable and incurable. It is not their business, they would argue, to make industry flourish; they have done enough if they let things take their course, good or bad.

But Mr. Carter entertains other ideas of his duty, and it is interesting to notice the experiment which he has been making for the weal of the settlement. Adjoining the Government-house at Bathurst were three and three-quarter acres of waste, ironically styled a garden. The annual estimates provided for two labourers to keep it in order, with the result that it was a wilderness of rank grass, the refuge of alligators, snakes, and all unclean things. Mr. Carter used his horse allowance in providing four labourers. He was then discharging the duties of the Superintendent of Police, and he devoted to the same public object the horse allowance appertaining to that office, which enabled him to set six men at work on this waste. The real interest of his enterprise is the fact that he sought to make the ground thus cleared a place for carrying out experiments as to trees and plants economically useful. He found that the rubber-

producing tree, the Ceara rubber, was well suited for the barren, intractable soil of the Gambia. In 1884 a large collection of plants likely to be acclimatized was sent out from Kew; and that which seemed best adapted for the trying climate was the Ceara rubber tree. The seedlings grew vigorously; the slips flourished equally. The great drawback was the want of good water; for in Bathurst there is no well which is not brackish. The rainfall is exceptionally small. Though 500 miles to the southward of the Gambia it is sometimes over 200 inches, in the Gambia the rainfall is rarely more than 50 inches, and for eight months in the year drought reigns. Botanical authorities seem to be sanguine that the rubber tree will thrive even in these unpromising circumstances. But, as the Director of Kew Gardens points out, the yield of rubber by each tree is trifling; several thousands would be required to produce for commerce an appreciable quantity of rubber. To infuse life and prosperity into the colony, and to make its people active producers and customers, other products are necessary; and Mr. Thiselton Dyer suggests that the cultivation of coconut, maize, cotton, and the fibre plants grown in the Bahamas, might be practicable. Mr. Carter showed what might be done in a climate which Europeans regard as an excuse for unvaried indolence; as to all action in which it is enough to say, as of the Reign of Terror, "I lived," "I started a garden in the Military Hospital compound, which produced most of the English salads and vegetables in great perfection, and which, I am glad to say, is still in full vigour. It was part of my plan to show that an English gentleman was not too proud or too indolent to work with his hands, for in the early morning and evening I prepared most of the beds myself, and trained a man in the proper method of working the system to advantage. . . . In spite of the brackish waters I have grown strawberries equal to the ordinary growths in England, and although the natural soil is the worst imaginable for the successful cultivation of roses, yet with judicious management I possess vigorous plants." So much for the miracles which energy may at all times work even in a desert or a Government-house garden in the tropics.

But without similar miracles, unfortunately, all are agreed that in the Gambia and so many other settlements nothing can be done. Our great colonies situated in temperate climes flourish lustily without aid or incentive. They quickly attain and in the end far surpass all that their founders ever dreamt of. But there are sad laggards in the march—settlements which are always promising better things, and always proving disappointments. Their industries never thrive. Emigrants to them are always sighing for home. Their crops are always blighted. Locusts seek them out, droughts infallibly scorch them. They vary stagnation only with an earthquake or a volcanic eruption. Their imports, closely examined, are seen to consist chiefly of munitions and luxuries for the garrison. The Gambia is one of those unfortunates, our Colonial poor relations, the incurables which are always under the care of the Colonial Office. Perhaps nothing can be done to mitigate their lot. "It is certain," says Mr. Carter, "that nothing can be done without the initiative of the Government," and it is not quite certain that much can be accomplished, where nature is at once so tyrannous and churlish and man so lethargic, with such initiative. But it would be interesting to see what would be the result of vigorous administration in some of our small African and West Indian settlements. Mr. Carter has got from the public funds by dint of much entreaty a contribution of £300 to carry out

his experiments. Mr. Thiselton Dyer pleads for a small annual vote, to be devoted in this settlement to the promotion of native agricultural industries, and argues that the effect would be beneficial. For our part, we should gladly see ten times as much spent were it likely that the sum would be spent with intelligence equal to that shown by the Administrator on the Gambia and Governor Moloney at Lagos. We should be certain that if the experiment were not entirely successful it would not be without good effect. Some wholesome plant would grow where only noisome weeds abounded, and there would be at least the example of strenuous industry, which would long continue to bear fruits even after the wells dug, the tanks built, the trees planted with public money, had ceased to exist.

EXPORTS AND PLANTING OF NORTH BORNEO.

(From the *British North Borneo Herald*, June 1st.)

TOBACCO, COFFEE, TIMBER, &c.

Today, we publish the Return of the Import and Export trade of the territory for the year 1888. These are comparative with the year 1887 and show the increase or decrease under each heading. The total Imports amount to \$1,261,997, being an increase of \$303,354 to over the year 1887. This satisfactory improvement in the Import trade is almost entirely due to the tobacco and other planting industries now established in North Borneo. A list of the Estates now in full operation may interest our readers:—

Marudu Bay and Banguay.	Tobacco	...	5
Do	do	Coffee...	2
Sugut river.	Tobacco	...	2
Labuk river.	do	...	1
Sandakan Bay.	do	...	2
Do	do	Coffee, Tobacco and Pepper...	1
Kinabatangan river.	Tobacco and Pepper	...	1
Do	Tobacco	...	1
Darvel Bay.	do	...	2

17

The Timber exports show a decrease of \$4,928 30 which is doubtless owing to the fact that those interested find it more remunerative to erect saw mills and saw timber in Borneo, rather than pay the extra freight and dunnage necessary in shipping unsawn timber. This refers particularly to cedars and soft woods, but in billian and hard woods there is an increased exportation. In the future our cedars and soft woods will be cut up by the two large saw mills in Sandakan Bay, one of which is in full operation and the other in course of erection.

In jungle produce, there is a decrease in damar and India-rubber, but under all other headings a satisfactory increase is well maintained and proves that our jungles are not yet exhausted, but the contrary, by opening up rivers and making roads as the Government is doing the exports of jungle produce will increase. Sea produce exports are also on the increase. This is particularly noticeable on seed pearls, where there is an increase of \$15,373 08 from the Lincabo fisheries. That the seas and bays around North Borneo all contain Seed Pearl Oysters (*Placuna Placenta*), Pearl Oysters (*Meleagrina Meragrinaferia*) (similar to the Ceylon Oyster shell but producing an inferior Pearl), Mother o Pearl Oysters (*Meleagrina Margaritifera*) and other varieties of Pearl producing shells, is beyond any doubt, and the finding, preserving and developing of them is receiving the attention of the Government.

The exports of tobacco are still small, but our readers will understand that tobacco culture in North Borneo is only beginning and that the crop for the year 1888 is yet in the fermenting sheds.

The Return of Foreign Shipping at Sandakan and the list of vessels and steam launches published with the Trade Returns show the rapid development in progress and we venture to assert that a country which in 6

years can show an increase in shipping from 1,205 to 4,260 tons with 12 estate launches and whose volume of trade, imports and exports, has increased from \$588,046 to \$1,787,862 will compare most favourably with any British Colony.

CHIEF EXPORTS FROM THE BRITISH NORTH BORNEO PORTS DURING THE TWELVE MONTHS ENDING

31st December 1888.			
Articles	Value.	Articles	Value.
	\$ c.		\$ c.
Birdsnests	42,274 77	India Rubber	18,698 86

PLANTING NOTES.

We have before us the prospectus of the Segaliud (Borneo) Tobacco Company Limited which proposes on a capital of £100,000 to buy 15,878 acres of land on the Segaliud River from the present proprietors, the British Borneo Trading and Planting Coy., who accept payment in £14,304 in cash and £33,330 in fully paid deferred and founders shares the first of which will not rank for dividend in any year until 10 per cent has been paid on the amount paid upon the ordinary shares. The founders share will receive no benefit until cumulative dividends of 100 per cent have been paid on the amount paid up on the ordinary shares when will be entitled to one fourth of the net profits after providing for a reserve fund of 10 o/o of the net profits in any one year.

COMPARATIVE PRICES OF INDIAN AND CEYLON TEAS.

We observe from the figures in Messrs. W. J. & H. Thompson's Annual Review that the following has been the course of prices for these rival growths during the last six years:—

Year	Average per lb. India.	Average per lb. Ceylon.	Difference in value per lb.
	s. d.	s. d.	d.
1883-84	.. 1 2 ..	1 4 1-10	.. 2 1-10
1884-85	.. 1 1 4-7 ..	1 3	.. 1 3-7
1885-86	.. 1 2 ..	1 2½	.. ½
1886-87	.. 1 0 ..	1 1½	.. 1½
1887-88	.. 1 0 1-20 ..	1 0½	.. 9-20
1888-89	.. 0 10 3-7 ..	0 10½	.. 1-14

Some people say that this season's Ceylon teas will fall in value below those of India.—*H. & C. Mail*, June 14th.

PLANTING IN LOWER PERAK.

Among the many energetic officials that our administration of the Native States of the Malay Peninsula has produced, there is none who has done more work or shown more energy than Mr. Noel Denison, the Superintendent of Lower Perak. He laid out Krian, and he may almost be said, with the assistance of Kinta, to have created Lower Perak. How he has pushed that district ahead, how it has grown and developed under his energetic management, is well known to those who remember what it was a few years ago, and see what it is now. To those who do not remember it as it was, only the annual returns of the last few years can give any idea of its recent development. Some idea, however, of the energy that has led to this development can be gained from the Annual Report of the Superintendent, which was published in the *Perak Government Gazette* of 31st May, and from which we gave numerous extracts in our last issue.

While we are assured by those who ought to be good judges, that Lower Perak is bound before long to be a great agricultural district, it must be allowed that its present flourishing condition is owing chiefly to the fact that the navigable portion of the Perak river runs through it, and that Teluk Anson, the chief town, is the source from which Batang Padang and the rich mining district of Kinta draw their supplies. In fact it is chiefly owing to the fortunate position of Teluk Anson as a port that Lower Perak flourishes and progresses. For some years it was the habit to disparage Teluk Anson, to say that it would never be more than a mere village, and that, when railways were introduced throughout the State, it would be bound to give place to the Dindings, and perhaps cease to exist. This was not the idea in Penang only, but generally throughout Perak. There were few who had any faith in Teluk Anson. Among those few, however, was fortunately the man principally interested in its progress. Mr. Denison believed in Taluk Anson. He thought it the proper outlet for the trade of all Lower Perak, Kinta and Batang Padang—the best source of supplies, the natural port. At first he stood almost alone in this. Officials and unofficials were almost all against him and in favor of the Dindings. With rare tenacity, however, he stuck to his point, and at last gained it. Those who were at first against him are now agreed with him: and we are therefore bound to take it for granted that he was right from the beginning. One of the most interesting parts of his despatch has reference to the projected railway, which we hope, ere long, will be an accomplished fact. At first Mr. Denison tells us it was only intended to be a light line from Teluk Anson to Tapah, a distance of some thirty-three miles. It has since developed into a plan for continuing it to Ipoh, about thirty miles further. As we said in a recent issue, the scheme has received the sanction of the Secretary of State: surveys and plans are completed as far as Jungkor, and by the end of August should be completed as far as Tapah. Mr. Denison expects great things from his railway. He expects the rapid development of Batang Padang, a country rich in mineral and agricultural resources, and that has remained so long undeveloped owing solely to the want of proper means of transit and communication.

The railway is Mr. Denison's pet scheme, and has taken up much of his time and thought; but it is quite evident that it has not done so to the neglect of other work. As keenly alive to the development of Lower Perak as to that of the districts beyond, he is doing his best to introduce pepper and padi planting on a large scale, and to induce Indian and Achinese planters to settle in his district. It is no easy matter evidently to deal with these people, and he has had trouble enough; but he recognizes the value of a settled agricultural population, and is not daunted by difficulties. In fact Lower Perak is agricultural or nothing. There are great forests and great swamps, and vast tracts of level country, containing, so far as we know, no minerals of value. So far, therefore, as the development of his own particular district is concerned, agriculture only can be looked to, and Mr. Denison is wise to encourage and foster it. With the splendid Perak river running through it, a railway in prospect, and roads opening up means of communication, we believe he is right in anticipating its development at no distant date.—*Penang and Straits Chronicle*, June 11th.

PLANTING IN DELI.

(From the *Straits Times*, June 26th.)

The firm of Lukwel and Tiel at Amsterdam do not make a rose-coloured view of tobacco enterprise in Deli last year. The quality of that article fell in many cases below the average, not only in the coast districts, but also in the more fertile inland estates. As to the latter, the consequent misgivings as to the future have been removed by better tidings regarding this year's crop. The tobacco from the coast

lands proved so inferior that it got very low prices in the market. Experience shows that this part of the country does not suit that line of cultivation. Any extension of planting enterprise in that section will only result in disappointment and failure. In fact planters would find it an advantage to strike their tents and move off to more promising fields betimes. This is specially applicable to Siak, where good tobacco grows on land whose productiveness soon runs out. Ignorance of this fact has led many persons to embark in tobacco planting there with hopes that have never been realised. In Palembang, the estates are yet too recent to admit of crops finding their way to market at present. Deli and Langkat continue to supply the best brands of tobacco, those from Serdang being distinctively inferior.

ALISMA PLANTAGO: WATER PLANTAIN.

The use of the root of *Alisma Plantago* or Water Plantain for hydrophobia appears by no means to be recent. Dr. Withering, in his 'British Plants'; 7th Edition, Vol. II., gives the following interesting note:—"This acrimonious blistering plant is said to resemble Crowsfoot in its general qualities. Cattle are sometimes much injured, if not killed by it, as atrophy and paralysis supervene. Gray states that the juice is used for drying up milk in the breast. The tubers are recommended in hydrophobia; especially in Russia, where their use was (in 1820) sanctioned by the College of Physicians of Moscow. The practice was subsequently made known in North America, and though specifics are not latterly in repute with the more enlightened of the medical faculty, it seems desirable to afford publicity to whatever may possibly relieve so dreadful a disorder." It is reported that an antidote to the poison of a rattlesnake was purchased by the Assembly of South Carolina from a negro, by giving him his freedom and an annuity of £100 for life. This remedy was derived from *Alisma Plantago*. Cattle that have eaten the *Alisma* have frequently become so paralysed that they could not stand. As death ensues from excessive stimulant action of the poison of the rattlesnake, and of the saliva of a rabid animal upon the muscular system, it is thought that a cure is effected by the peculiar sedative power of *Alisma* relaxing the spasms, and that it will be found effectual for the cure of these two dreadful maladies, as also of tetanus. The best mode of administering it, when the difficulty of swallowing comes on, is to scrape about an ounce of the solid root and let it be eaten between two slices of bread. The dose being repeated in an hour if spasms are not relieved. (Withering, Vol. II., page 404). Further investigation with regard to the active principles of the root might be useful.—*Monthly Magazine of Pharmacy*.

BOERHAAVA DIFFUSA.

By W. A. JAYESINGHA,

Surgeon to the Civil Hospital, Kurunegala, Ceylon.

The *Boerhaava diffusa* is a common perennial procumbent weed, with opposite, more or less unequal, ovate or cordate leaves and loose pinacles of small red flowers, collected on small heads; it belongs to the natural order *Nyctaginaceae*, and is known in Sinhalese as Pitta sudu pala, and in Tamil as Mookorota, and was tried by me as a diuretic in the Government Civil Hospital, Kurunegala.

According to Dutt, the root is regarded as a laxative and stomachic used in jaundice, ascites, anasarca, scanty urine and in internal inflammation.

Sub-Assistant Surgeon B. M. Chatterjee reports having found it a very good expectorant, and that he has prescribed it in several cases of asthma, with marked success. He employed it in the form of powder,

decoction and infusion, but the doses and the proportions are not furnished. Taken in large doses it is said to act as an emetic.

The mode of administration adopted by me is the following, namely: two ounces of the plant are infused for half-an-hour in a pint of boiling water and strained. This quantity is administered in divided doses to one patient in the 24 hours.

The practitioners of Native Medicine in Ceylon consider it as one of the best medicines in dropsy, and give it in the form of a decoction, and locally as a fomentation in inflammation and rheumatism.

Then follow the results obtained in nine cases in which the use of the infusion of *Boerhaava diffusa* was indicated.—*Christy's "New Commercial Plants & Drugs."*

COTTON CULTIVATION.

The cultivation of cotton is not a new industry in Ceylon. It was carried on to a large extent in former days, and was only allowed to die out because, owing to various reasons, there came to be no sufficient market for the produce. This difficulty has been removed by the establishment of a Company in Colombo, which agrees to buy all the cotton that can be produced. The soil and climate of a great part of Ceylon appear to be well adapted to the growth of cotton; the cultivation is an extremely easy one; and the plucking of the pods and the removing of the seed from them will give employment to the women and children of the village. There is little doubt that cotton cultivation will pay; and there is no reason why every village garden and a large proportion of chena lands should not be planted with it. Now that coffee has died out, it is very important that the villager should have some other product to plant which will bring him money.

Cotton seed will be provided free of charge at every kachchéri to any native cultivator who applies for it, and the first outlay for the cultivation will thus be materially reduced. All cotton grown by the villager will be paid for at a fair price at the nearest large village to his land.

Some hints for cultivating cotton and some results of actual experiments are given below. It must be clearly understood that these are not final. When the cultivation has been carried on for a year or two in many different places, it will be much easier to draw up a set of final rules on the subject. But if the rules now given are adhered to, and if the villager will follow these hints and try the experiment, he can at least lose nothing, and it is fairly certain he will gain a great deal.

The species of cotton recommended for cultivation are the American (including Sea Island), Egyptian and Peruvian (ordinary native) cotton.

"*Kapu,*" or *Peruvian Cotton.*—Villagers who know this cotton should give it there careful attention, as a ready market can at all times now be found for it. This variety of cotton grows for several years, gives the least trouble of all the varieties, and will grow in almost any situation.

There appears at present to be no reason why dry grains and cotton should not be cultivated together on the same land. The advisability of doing so must, however, be tasted by experience.

I.—HINTS FOR CULTIVATION.

(Applicable to American and Egyptian Cotton.)

1. The richer the soil the better. Avoid shade. Chena land, even though steep and rocky, is suitable.
2. The seed being very oily loses its vitality quickly. Do not allow it to become damp, but keep it spread out in a cool place. Sow as soon as possible after its receipt, but wait for a wet day.
3. It is of primary importance to sow at such a time as will result in the crop being ready for picking in dry weather; secondarily, the seed must be planted on a showery day.
4. Two pounds of seed are sufficient to sow one acre.

5. Plant the seed in places 3 ft. by 3 ft. or 3 ft. by 4 ft. apart. Before planting break up each place with a fork or momoti, 4 to 5 in. deep and 6 to 8 in. square. Plant two seeds, 3 to 4 in. apart, in each place at a depth of not more than 1 in.

6. If one out of every two seeds grows, there will then be 4,800 plants to an acre if planted 3 ft. by 4 ft.; 3,600 plants to an acre if planted 3 ft. by 3 ft.

7. In those parts of the Island affected by the south-west monsoon the season for sowing is approximately from July 1 to August 15, but in those other parts depending on the north-east monsoon for agricultural operations, the proper season for sowing will be when those rains set in. The crop will be ready from January 1 onwards. The American variety ripens two to three weeks earlier than the Egyptian.

8. Pick the cotton when the capsules burst, leaving the capsules on the tree.

9. Thoroughly dry the cotton in the sun, clean it, and separate it from the seed.

10. The cotton should be separated from the seed by a gin, which is easily worked, and very cheap.

11. Be very careful not to break up the seeds in the cotton.

II.—RESULTS.

1. Uncleaned cotton of 612 pods (American variety) weighed 3 lb. 8 oz. It was then separated from the seed: the weight of the seed was 2 lb. 12 oz., while the weight of the cotton was 12 oz.: therefore (deducting 12 pods for wastage) 50 pods produce 1 oz. clean cotton.

2. 4,433 seeds (American variety) weighed 1 lb. One acre, planted 3 ft. by 4 ft., two seeds in each place, requires 7,200 seeds; therefore two pounds of seed are sufficient to plant one acre.

3. The largest number of pods counted on one tree was 130. The largest number of pods counted on two trees planted in one hole was $128 \times 104 = 232$.

4. Thirty pods are a very low and safe estimate of the average produce of each tree. Assuming that on one acre planted 3 ft. by 4 ft., two seeds in each hole, only one out of every two seeds grows, we have 3,600 plants \times 30 pods = 108,000 pods = 2,160 oz. = 135 lb. clean cotton.

INSTRUCTIONS TO INTENDING COTTON GROWERS

IN NATAL.

(Issued by the Natal Chamber of Commerce.)

1. Plough, dig or hoe, as deeply as possible, the land intended for cotton, so as to admit the air thoroughly.

2. Sow the seed by string line, which makes hoeing and weeding easier. The rows should be five feet asunder. Drop two or three cotton seeds together at intervals of four feet along the lines. The seed need not be buried deeply, but should be covered lightly with mould. Care should be taken not to trample on the spot where the seed is deposited. Sow from the middle of September to the middle of November.

3. The plants will appear above the ground in from seven to ten days, and when they have four distinct leaves thin them, leaving the strongest of each group of three.

4. Weed carefully for the first six weeks or two months and draw up the earth about the stems until the blossoms appear.

5. When the plants are from six weeks to two months old nip off about an inch from top of each shoot. This will cause the plant to throw out a greater number of branches, and consequently it will bear a larger crop. Repeat this process a second and even a third time in the first season.

6. The blossoms usually appear in about 80 days, and the pods arrive at maturity about three months after sowing.

7. After the first year it is advisable to have an undergrowth of vegetables. These in high winds keep the dust from soiling the cotton when the pods begin to open. If soiled the cotton loses greatly in value.—*Natal Mercury.*

THE AMSTERDAM CINCHONA AUCTIONS.

(Telegram from our Correspondent.)

AMSTERDAM, June 13th.

Of the cinchona offered by auction today, particulars of which were given in our last issue, 2,051 were sold, at an average unit price of about 7 cents per $\frac{1}{2}$ kilo. (equal to $1\frac{1}{4}$ per lb.) Manufacturers' bark, in quill, broken quills, chips, and shavings, sold at 10 to 68 cents (equal to $1\frac{3}{4}$ to 1s per lb.); root at 10 to 18 cents (equal to $1\frac{3}{4}$ to $3\frac{1}{4}$ d.) Druggists' barks in quills, broken quills, &c., brought from 7 to 50 cents (equal to $1\frac{1}{4}$ to 9d), and root from 7 to 54 cents or $1\frac{1}{4}$ to $9\frac{3}{4}$ d per lb. The principal buyers in order of precedence were the Amsterdam Cinchona Works, the Brunswick Factory, and the Auerbach Factory. The result of the auction shows some decline on the last auction rates.—*Chemist and Druggist.*

JAVA: CINCHONA PLANTING.—Judging by their annual reports and balance sheets—says the *Chemist and Druggist*—a good many of the Java cinchona plantations have been doing pretty well last year and do not at all appear to regard the commercial position of their product as desperate. The Soekaneegara Company announce that in 1888 they have made a sufficiently large profit to cover the loss of the previous year, and to leave a fair residue. The uprooting of officinalis trees in the gardens of the company is being continued, and the vacant places are being filled with the richer ledger trees—the average sulphate of quinine equivalent of the ledger stem bark from the company's gardens having been 6.91 per cent last year. The whole of the product of the Company in 1888 has been sold to the Brunswick Quinine Works, at an average price for the equivalent of quinine of sulphate in the bark of 18.13f. per kilo., or $10\frac{1}{4}$ d per oz. The Melattie Company, which last year harvested a bark averaging 3.85 per cent quinine sulphate, gives some particulars of the cost of production of this bark, from which it appears that the bark has cost for rent and taxes of soil, harvesting, curing, packing, freight to Holland, and sale expenses there, 41.81 cents per kilo. (equal to 3 13-15ths d. per lb.) The average net sale price was 65.97 cents (equal to 5 14-15ths d. per lb), leaving a profit of 24.16 cents (equal to 2 1-15ths d. per lb), or about 57 per cent on the cost price. The company's report states that at a unit of $1\frac{1}{4}$ per lb ($8\frac{1}{2}$ cents) all bark analysing over $1\frac{1}{2}$ per cent quinine sulphate can be harvested at a profit. On the Melattie estate also the poorer trees are being steadily replaced by richer plants. A dividend of 9 per cent was declared by this Company.

Kew.—Kew is, as it always is, full of interest, and even fuller of beauty than usual. Among the plants in bloom are *Gerbera Jamesoni*, a Natal Composite like an *Arctotis* with sinuate leaves, and flowerheads nearly 2 inches across, of an orange-crimson colour. *Rosa simplicifolia* is a great curiosity, and a very elegant one having slender stems, leaves glaucous, reduced to the terminal leaflet only, and small yellow flowers, each petal provided with a brownish-purple spot at the base, so that the flower looks more like a *Cistus* than a *Rose*. *Satyrium Hallackii* is a noble terrestrial Orchid from Natal, with broad leaves, like those of an *Hæmanthus*, and a stout erect spike capped by a dense pyramidal spike of crimson flowers. That very extraordinary and certainly not handsome *Acanthosicyos horrida* is thriving, as well as two or three *Welwitschias* some eight or nine years old. For those to whom these have no charms the flush of Bluebells under the group of *Araucarias* near the Palm-stove will be as to every one else deliciously attractive. The beds of Parrot Tulips are still very showy, and the patch of *Primula japonica* on the wild mount very remarkable. The alpine-house is a blaze of beauty, but we trust the Directorate will keep it as an alpine-house or a house for the display of such plants as can be grown without artificial heat, or its *raison d'être* will be lost. As to the rockery—well—go and see.—*Gardeners' Chronicle*

THE XL ALL TEA MACHINE.—An estate proprietor writes:—"Just ordered from Edinburgh an XL ALL, large size. I am now convinced that I am right in accepting this as the machine for a poor planter in cloud-rolling valleys of mist and drizzle, for it simply defies the elements. I can give you chapter and verse too for this, but what a hunt I have had for it."

TEA NOTES.—Chittagong, 15th June.—The rains set in on 10th June, since when, there has been continued cold, showery weather.—Charali, 18th June: We have had two bright days without rain, but this morning it is as per usual, raining. Mosquito, red spider and green fly seem to like it and are flourishing.—Dehra Dun, 19th June: There has been nothing of any importance to note the last few weeks. We had heavy rain on the 9th and it rained hard all last night and is still pouring. We ought to have an early and good crop these rains. Sonari, 16th June.—Rain registered every day this month. Total to date 47 inches. Soil saturated with moisture, and growth of leaf has been checked. Quantity will suffer during June, and quality still leaves much to be desired. Temperature, somewhat higher within the past week, but more sun wanted.—Sootea, 17th June: The weather, since about the 10th instant, has been the most favourable that we have had since general plucking commenced. All the gardens, however, and particularly those situated on high land, have not responded to the change as yet. The fly and spider are still very severe. On plots where the latter pest is rampant, handfuls of old shed leaves are lying below the bushes.—Dibrugarh, 17th June

Rainfall this month	...	10.96 inches.
Total to date 1889	...	47.73 "
" " 1888	...	54.85 "

The return of leaf for the week was still short, but as warmer weather has now set in, it is hoped the second half of June will yield better. Taking the district as a whole, the return is still well ahead of last year.—Darjeeling, 21st June: Nothing but rain and fogs: sunshine for the week about 5 hours. If more of the latter and less of former were to appear, a good flush might come on as it is leaf in upper portions of gardens is standing still. Rainfall 25 inches against 12 inches in 1888. Our latest telegram from Darjeeling is:—Heavy rain yesterday and today. Tea blights much the same, diarrhoea amongst coolies better throughout district.—*Indian Planter's Gazette.*

ANTIARINE.—At the meeting of the Linnean Society, on June 6th, Mr. Thomas Christy, F.L.S., showed the succus or milk, also the antiarine, with the plant *Antiaris toxicaria*. This antiarine is likely to become an important feature in commerce. It has hitherto been obtained from the Upas tree, which grows in Java. According to Dr. Trimen, of Ceylon, however, there is a large number of antiaris grown in that country, and should that variety turn out to have toxic properties, even if not so strong as the tree that grows in Java, it will be of great importance to the Colonies. At the present time large quantities of the *Antiaris toxicaria* are being distributed to our Colonies, with a view of their growing the plant. Mr. Christy also showed the strophanthus plant, which is a glabrous variety from the Gaboon, and which yields the African arrow poison. The texture of the leaf of these two plants is almost identical. Enormous fields remain open at the present time for introducing the plants which Mr. Christy is growing at Sydenham, which he receives from South America, and all of which would do well on the highlands of Ceylon and India, and yield large returns, owing to the high prices put upon the drugs. It may not be useless to say that at the present time supplies of these South American drugs are being drawn from private gardens in the South of Europe.—*Colonies and India.*

TEA PLUCKING: FINE AND MEDIUM:

PUTTING BOTH TO THE TEST AND THE RESULTS.

We have been favoured with a statement of the experience of a gentleman with a keen interest in this question and who, as a business man, has been working in connection with two well-known upcountry planters in certain experiments to test 'fine' and 'medium' plucking and manufacture. These experiments can scarcely yet be said to be completed; but so far, the result,—when reduced to rupees, which is after all the only satisfactory test—is decidedly in favour of medium plucking. Indeed in the case of two estates (one in Dolosbage and one in Ambagamuwa) the finer plucking, although certainly a loss of 30 to 35 per cent in yield, has scarcely increased the average price one cent. The weak points about the experiments is, first, the difficulty of valuing the tea for comparison with the old style of plucking, and second, the uncertainty as to whether there will be a permanent loss of 30 to 35 per cent, or whether the trees will adjust themselves to the new style of plucking. One of the planters concerned thinks the latter; the other is doubtful. The uncertainty in value arises from the present irregularity of the market, and there have been some most extraordinary discrepancies between the local opinions and those of the London market. It is the opinion of some that it is possible to make the finest tea from any estate if planters only pluck fine enough; but this is not the case: and it will, we suspect, be found that each estate must experiment for itself. In most cases 400 lb. (medium plucking) can be plucked for the same money as 300 lb. fine. It would therefore appear that the extra 100 lb. costs nothing to pluck and if the planter can manufacture it without injuring the quality of his finer leaf, he can afford to sell it for the manufacturing charges and transport (say 15 cents). It is therefore quite a mistake to imagine that Ceylon Pekoe Sou-chong at even 5½ is entailing a loss.

PLANTING PROSPECTS: TEA AND COFFEE!

(By an Old Planter.)

I am afraid tea is in a bad way, and it will soon be a case of the "survival of the fittest." Estates planted on new land have the best chance, but those raised on old and in many cases worn-out coffee estates, with the old coffee debt as an additional incubus, cannot, I should think, survive the coming struggle (spell struggle with three *g*'s to intensify it!). Most of the Dimbula, many of the Dikoya and all the Maskeliya estates I do not characterize as old; they were not in coffee long enough to exhaust the soil, and were, moreover, as a rule well drained and hand weeded from the commencement: no "mamoty" or "karandi" being permitted to desecrate the *humus* and scrape it away. I am a great believer in the first six inches of a soil: to me it seems essential to the vigorous growth of a plant, and although tea is a very hardy plant and will grow on soils without a particle of *humus*, yet to my mind it can never have the stamina and sound constitution of the plant raised on virgin soil. Stunted in youth it grows up like the animal that has been ill-nourished in infancy, and any amount of doctoring in after life cannot give it what it lost in early life.

Tom Gray's order to grow a sucker on his coffee stump; comes I should think a little too late. Surely by this time the tea has possession, and the coffee stumps hacked and knocked about so that they can have very little life left in them. Even if successful, *cui bono*? Leaf-disease will not permit it to bear. Some people talk of leaf-disease leaving or becoming less virulent. Well, no doubt at times it seems as if it had taken its departure or had satiated its

"voracious maw;" but when least expected to thrive it is as fresh and sap-thirsty as ever! This year I am sorry to say some Liberian coffee that I have seen in the lowcountry is affected almost as badly as I have ever seen it. Coffee raised from the Mysore or other strong varieties and grown under shade should I think stand a good chance of success. I would not, however, plant under the forest shade, but grow suitable trees for the purpose, this would make one quite independent of forest land. On the Uva side coffee might be grown this way up to 3,500 ft., and on the Kandy side up to 2,500 ft. elevation; higher altitudes would hardly give crop enough. I know patches of Liberian coffee in the lowcountry under shade which crop fairly, and are not much troubled by leaf-disease. It would be worth some one's while to try a small experiment.

WHAT A SINGLE GRAIN OF RICE PRODUCED.

There came up in my garden in a hole of water, may be six inches deep, a single grain of rice. It produced more than 90 heads at the first crop and over 110 heads for the second crop. The first crop was stripped from the heads and the grain poured into water and the imperfect grains floated off. Then the mass was measured with a spoon. The spoon was then filled three times and each spoonful counted by itself. The three were then added and an average struck. Equal care was bestowed on the second crop. The whole number of grains from that one grain I found to be 25,706.—*Florida Dispatch.*

COFFEE AND TEA.

CAUSE OF THE CHECKING OF TEA FLUSH—CHANGEABLE WEATHER—TEA AND COFFEE IN DIMBULA LOOKING WELL—COFFEE AND CINCHONA ON BELGRAVIA—THE HOPES OF PLANTERS REST ON TEA—COFFEE LEAF DISEASE DUE TO A WORM AT THE ROOTS!—COFFEE IN BRAZIL.

NANUOYA, 8th July 1889.

The checking of tea flush in this region to a greater extent even than is usual in the South-West monsoon seems due this season, not so much to rain, which is rather below than above the average, but to the prevalence of strong cold winds. Wednesday, the 3rd, was a comparatively fine day, only 7 cents of rain falling. Next day gave 33 cents, and Friday, with 60 cents measured, was the very type of dreary darkness and cold drizzling wind. "Fine planting weather set in," was the decision, but even planting was conducted under difficulties. Saturday showed only 6 cents of rain against the 60 of the day before, and yesterday the reaction was complete to a model Sunday of bright cheerful sunshine and warm genial temperature. The mountains, forests, patanas, streams and cultivated lands looked fresh and beautiful. If similar weather continues, it will have the opposite effect of trying the plants "put out" and of stimulating tea into flush again. Tea looks well except that there is more blossom than is desirable on fields which were pruned 14 months ago, or more, while a few scattered spots have been affected by green fly. In some parts of Dimbula coffee is looking well, the fungus not being so apparent as the berries. The lower elevations are, of course, the more favoured; but yesterday I saw some very fine coffee on Inverness at an altitude of 5,300 feet and over. On Wednesday I travelled the last portion of the railway journey with a planter who had just left Belgravia, and he reported a crop of 7 cwt. per acre on the coffee trees and the proprietor busy planting out ledgerianas. Belgravia, it must be remembered, had good soil, aspect and elevation to begin with, and the effect of the large quantities of manure applied to it in the palmy days of the

coffee enterprise must still and for many years yet tell in favour of the cultured plants. In most cases, however, there is no encouragement to preserve such coffee bushes as remain in the district. Our hopes must rest on tea, and a rebound from low to high prices, such as so frequently marked the history of the coffee enterprise. By the way, planters in Ceylon must be surprised to learn that "scientific men," according to the *Rio News* and other authorities, have come to the conclusion that coffee disease in Java, Ceylon and Brazil is identical, caused by "a worm which eats the roots." White grub, no doubt, did harm to our coffee, but the fatal disease was due to a fungus, and if, in addition to the insect diseases they suffer from, this vegetable pest finds its way to the plantations of Brazil, the world's supply of coffee may be so lessened as to tell greatly in favour of tea.

OPENING OF FOOCHOW TEA MARKET.

The *Foochow Echo* of the 8th instant says:—The stock of new tea now amounts to 225,000 chests of all sorts. It is not expected that musters will be sent out for another week. The *Foochow Echo* learns that new season's new make congous, costing 8d. a 9½d. (and which looked so cheap in China,) are losing 20 per cent. The London market for new teas appears to have opened at about 30 per cent. under last year. Mr. W. P. Galton writes the following letter, dated 5th June, to the *Foochow Echo*:—

Sir,—It may be of interest, at the present time, to draw attention to the comparative dates of opening the tea market, and the stocks of Congou at that time; dating from 1869, when steamers were first introduced; the "Achilles" and "West Indian" loading for London.

Those who have experience of the past can draw their own conclusions.

Year.	Date of opening.	Stock of Congou.
1869	June 25th	276,927 Chests.
1870	July 1st	245,112 "
1871	June 13th	133,070 "
1872	May 24th	50,705 "
1873	June 20th	258,430 "
1874	do 2nd	96,630 "
1875	May 19th	2,550 "
1876	do 20th	2,560 "
1877	do 24th	40,004 "
1878	do 14th	47,960 "
1879	June 6th	282,612 "
1880	do 5th	291,030 "
1881	May 23th	83,110 "
1882	do 29th	155,040 "
1883	June 11th	333,700 "
1884	do 6th	310,000 "
1885	do 20th	329,000 "
1886	May 24th	175,000 "
1887	do 30th	165,500 "
1888	do 30th	117,700 "

CINCHONA BARK:—WANTED: A SYNDICATE OF CINCHONA PLANTERS TO REGULATE SUPPLY OF BARK TO EUROPE DURING 1890-91.

Our heading in brief summarizes the purport of the important letter addressed to us by Baron von Rosenberg which will be found (on page 136.) It is addressed to the Editor of the *Tropical Agriculturist*, but without waiting for the next issue of our monthly periodical, we at once give it a place in our daily paper, so as to ensure its consideration and discussion by our planting and mercantile community interested in cinchona as early as possible. The Baron von Rosenberg must, of course, be aware that very numerous have been the attempts made through the press to check the free harvesting of cinchona bark during the past few years. It has been

shown again and again and with fuller demonstration than even our correspondent today affords, how much better it would be for the cinchona producers if they did not force so large a quantity—and especially of the inferior qualities—of bark on the European market during each succeeding year. There has not been a shadow of a shade of dissent from this proposition; but nevertheless year by year, the export has gone on increasing far above all estimates, the simple but all-sufficient explanation of the Ceylon planter being.

My poverty, but not my will consents.

With his coffee ruined, and his tea not yet in bearing, the hardly-trying planter in this island had to cut his cinchona bark to get any money at all to keep his work going. With an increasing area giving crop under tea, and with the great additional claim on the time and attention of planters and coolies necessitated by tea, and also no doubt with the greatly contracted area under cinchona, this year at last has seen an appreciable diminution of the exports of bark. Still, compared with last year, the reduction is not much, and it is very certain now that do what we may our estimates for the season ending 30th September next is to be exceeded. We estimated 9 millions lb. as our total export for season 1888-89; but to the 4th instant we have shipped 8,445,013 lb. So that it is pretty certain the total outturn will be nearer 10 than 9 millions. This, however, would indicate a substantial reduction on the past three years, as the following comparison will show:—

Exports of Cinchona Bark from Ceylon:

Season 1888-9 (say)	10,000,000 lb.
Do 1887-8	11,704,932 lb.
Do 1886-7	14,389,184 lb.
Do 1885-6	15,364,912 lb.

For next season—1889-90—already an estimate of 8 millions of pounds has been put forward, and although the total amount of available bark in this island has undoubtedly been very largely contracted by the enormous exports of the past four years—due to the hard times for planters and their supplantment of cinchona by tea,—still it is almost certain that 8 millions lb. at least will be shipped, unless some movement takes place such as that suggested by Baron von Rosenberg to regulate and reduce the harvesting and exports.

Is it then feasible to form a Syndicate, or adopt an Agreement embracing the Cinchona Planters of Ceylon, India and Java to regulate their supply of bark to Europe during, say the next two or three years? Some time ago, we think the suggestion would have been laughed "out of court" in Ceylon. But that was when the whole of our hillcountry nearly was covered with cinchona in various stages; that was when the crisis following the collapse of coffee was at its height; and again it was at a time when most of us thought that the only chance for Ceylon was to get its bark into the home market before Java or India began to harvest largely. Now, the whole aspect of the cinchona question has altered both here and with the other two great Eastern competitors. The area under cinchona—the number of holders of bark—in Ceylon has contracted enormously. Cinchona has been entirely cleared out of many districts, and it should not be difficult to form all the proprietors or agents holding appreciable areas of harvestable bark into an Association for the purpose desired by Baron von Rosenberg, as far as their personal subscription to the proposal is concerned. How the practical work of regulating the cropping and export would be managed, is a matter we do not discuss for the present. Again so far as acquaintance with their resources—the extent of their planting and quantity of available bark—is concerned, we know

far more of Java and of Southern India now than we did some time ago.

The best opinion that can be formed of our supply in Ceylon, places the total of available bark—if it became necessary to cut down and root up all our trees—at about 20 millions lb. We have Mr. Hamlin's authority for supposing that the total for India if treated in the same way could not exceed this figure of 20 millions lb. As for Java, we have the results of the very elaborate and careful inquiry made by the Soekaboemi Planters' Association which we are publishing in full in the *Tropical Agriculturist*, and it shows that the total export of bark from Java for 1888 was put down at 3,689,000 lb. (averaging 4.11 per cent quinine) and for 1889 at 4,522,990 lb. (averaging 4.16 per cent). In Java, we may say, the planters do regulate their output far more carefully than do their brethren in Ceylon. The Java planters do not harvest until they consider that they can get about the maximum of benefit from their bark. So that after all the practical question would seem to be how to regulate, that is, reduce, the export from India and Ceylon. Still if the Java planters entered the Agreement to keep their exports for 1890 and 1891 at not more than $3\frac{1}{2}$ to 4 millions lb., there would be a distinct advantage. By what means then can we secure a reduction of the Ceylon exports for each of the two seasons in the Agreement to from 5 to 6 millions of lb. and of India to from 3 to 4 or even 4 to 5 millions? This is the practical problem. It will be for the larger holders of bark in Ceylon to give it their best consideration in response to Baron von Rosenberg. The Badulla Planters' Association is perhaps the one most intimately associated with the largest area under cinchona left in the island. Udapussellawa and the Agras division of Dimbula are almost the only other two districts needful to take into account. Could it be possible to get all owners of say more than 30 acres of cinchona in Uva and the two districts mentioned, to agree to restrict their harvesting to a certain rate per acre, during the next two years?

EUCALYPTS AND OTHER FUNGI TREES ON HILLS OF CEYLON.

WET WEATHER—GROWTH OF TOONS, EUCALYPTS, AND CRYPTOMERIAS—THE NORFOLK ISLAND PINE—JUNGLE TREES IN FLOWER—THE NUWARA ELIYA PLAIN—A VISIT TO HAKGALA.

NANUOYA, July 10th.

Yesterday morning promised fair in Dimbula, and the rainfall was not heavy, only 19 cents being measured this morning. But driving up to Nuwara Eliya though the valley and gorges of the Nanuoya we experienced one of those storms of drizzle and mist-laden winds, which are more pleasant to recall and talk about than to go through, although such weather has really no evil effect but the contrary on those who are well clad in waterproof coats and boots. The most disagreeable effects in our experience was from the drip in pushing through our little forest of toons (*Cedrela Toona*) and Japan pines (*Cryptomeria japonica*) and other trees near the bund of the Lake. The effect of the massive red tops of the toons on the hillside facing the Lake is now very fine, and the rate at which the trees have grown vies with that of the Australian *Eucalypti*. In the first two years a measured tree had made 22 feet in height. This rate has now been somewhat lessened because the trees have to thicken their branchless stems, but the tree we measured yesterday was 27 feet high, so that in September, when the third year from planting out will have rounded off, the growth will be 30 feet, or 10 feet

per annum. The *cryptomerias* have made slower progress, having in their earlier stages received unwelcome attention from hares and rats. But now that the early troubles are over their growth is very luxuriant, too much so in the case of the side branches, which will be trimmed off and used as cuttings, the tree being easily propagated in this manner. A correspondent who recently wrote must have mistaken this really handsome pine for *Araucaria excelsa*, the Norfolk Island pine, of which, I regret to say, plants are not available at Hakgala. It is one of the grandest trees in the world, but difficult to propagate from seed. On Abbotsford a root shoot has been successfully removed from the closely allied *Araucaria cookii* and promises to become a fine tree. A good many jungle trees were in blossom as we ascended through the Nanuoya forest; and in consequence of the nilu having died down, the more open spaces up the hillsides were blazing with the blossoms of the common indigenous balsam. A very considerable number of the abounding rhododendrons were in blossom, and what this tree could become under cultivation is shown by a splendidly coloured and beautifully formed specimen, which stands conspicuous on Mr. Robertson's cleared land at the entrance to Nuwara Eliya. The large old cherry trees scattered about the plain were also in magnificent blossom, and when the weather cleared up at noon, the place looked quietly beautiful, with the great mountains looking lovingly down on their own reflections in the waters of the Lake, on the cottages and gardens and on the river winding through the green Plain. We availed ourselves of the grateful change to visit Hakgala; and we were repaid, apart from the beauty and interest of the gardens by a glorious view of the Uva valleys and mountains. The Haputale range was specially clear, and the railway cuttings along the ridge which leads to "the Pass" seemed quite close at hand. Many additions have been made to the mountain gardens since we visited them last, and alterations and additions are still being made. We were interested in the recent introductions by Mr. Nock of fruit-trees, vines, camellias, azaleas, &c., our only regret being that the able and genial head of the establishment was not present. In his absence we were well ciceroned, first by a young Sinhalese who explained every familiar as well as strange plant to us, as if we were perfect strangers not only to the country but to the vegetable kingdom, and subsequently by Mr. de Alwis. Amongst the most striking objects were China bananas in rich flower and the fine old specimen of *Pinus longifolia*. The Hakgala gardens promise greatly to increase in attractiveness and value.

COFFEE AND TEA.

REVIVAL OF COFFEE—COORG COFFEE SEED—AN OLD BOOK ON MANURING AND QUALITY OF TEA—TEA CULTIVATION AND PREPARATION BY THE CHINESE—THE WEATHER. 8th July.

The belief that *Coffee* is going to have a turn again seems to be pretty general among some classes of the natives, but it does not go very much further than talk. Meanwhile what is growing is just about developing as nice an attack of leaf-disease as anyone would like to see; still the crop is not much behind last year, albeit there was but one blossom to speak of.

If Coorg coffee seed could be easily had there would doubtless be more trial extensions than there are, but to get the seed is the difficulty. There is a good chance here for someone to start an agency for supplying this.

Whether Coorg seed is better, however, than our own is a moot question: some who have grown it say no; but if a man does believe in it, he is always assured of the first three years of hope. Every new estate as we know lays that gift at the feet of its possessor, which is sometimes all it ever gives. Still to have that assured is something. Reading an old book published in 1848:—"An Account of the Cultivation and Manufacture of Tea in China," by Samuel Ball, who was Tea Inspector to the Hon. the United East India Company,—I came upon two passages on the effect of manure on tea, which was one of the subjects in your late questions. It was the one which perhaps most who answered felt their ground least certain, especially in regard to its effects on flavour. It is of black tea, the writer is speaking and this is what he says:—"The Chinese universally affirm that manure is not employed for that tea, and is injurious to its flavour." In another place there is this passage:—"It will also be seen under the article '*Green Tea*' that an immense improvement was effected in that tea by transplanting it from the hills into the plains, and by cultivating it in garden soil fit for vegetables; moreover by the use of manure. *The black tea however is not manured.*"

Those who don't get very high prices for their teas, spite of their best endeavours to produce good ones, may get a little comfort from the standpoint of the Chinaman on the question of quality. In Mr. Ball's work, he quotes the following from the testimony of a Spanish missionary to the Chinese, who had written an account of the tea plant:—"In the province of Fo-Kien there are many plantations, where the care and method of preparing tea are nearly the same, whilst the tea is very different, whether we consider the leaves, the flavour, or the effects it produces; consequently the nature of the soil cannot be the same. The Chinese themselves sufficiently prove this, by their frequent declaration that the *Ty Tu* or soil occasions the principal difference in the quality of tea." Mr. Ball has a note to this passage which runs thus:—"This observation is confirmed by my own enquiries. Ask a Chinese what causes the difference of quality in tea, and his reply invariably is, the *Ty Tu*, *i. e.* the soil."

There are I think few tea planters in Ceylon, limited as is their experience compared with John Chinaman, but have found out for themselves that the leaf from particular fields in their estates makes a better tea than from others; nevertheless it is not unpleasant to have one's original observations confirmed by such old world knowledge of the fragrant shrub, as is possessed by the celestial.

The weather is now getting more favourable for flushing than it has been for some time lately. If we could be spared the worrying wind, we would be all more fully employed in our factories than we have been for some weeks past.

THE STRAWSONIZER:

IMPORTANT TO COFFEE AND ALL OTHER PLANTERS
TROUBLED WITH INSECT OR FUNGOID PESTS.

We are indebted to the friend who has called our attention to the following paragraph in the *Calcutta Asian*. We would ask that one or other of our enterprising local firms, do kindly make enquiries about this machine *pro bono publico*, and if they see their way, import one which could be let out to travel in the planting districts after the fashion of reaping and threshing machines in agricultural districts in Britain? We quote as follows:—

The Strawsonizer is a machine which has added a new set of words to the English language. As a matter of course, the success of the invention has led to the formation of a Limited Liability Company, of which it is unnecessary to take notice in this place, except to observe that the inventor, Mr. Strawson, gets £25,000 for his machine, with a royalty of 2½ per cent on sales. The great utility of the machine was immediately recognized by English agriculturists, and a public trial of it, on one of the Royal farms at Windsor, has given an opportunity to the world at large for becoming acquainted with it. It seems to be likely to be of considerable service in India, especially to indigo planters, and if the factories in Behar had been equipped with Strawsonizers a few months ago, the invasion of the caterpillar, which did so much injury to the young plant, would have been promptly checked. The following description of the machine is taken partly from a notice in one of our London contemporaries: The Strawsonizer is a machine of light construction, resting upon two wheels, and easily drawn by one horse. By means of a multiplying gearing, the revolutions of the driving-wheels are communicated to a fan, which makes from 2,000 to 3,000 revolutions in a minute. The fan is axled within a tube, from the hinder end of which there issues a powerful blast of air; and this blast, by catching the stream of solid or liquid material discharged from a hopper above, scatters such material in a fashion which has never before been seen. By a few slight alterations and adjustments, the same machine can be used for the distribution of liquids or solids. The machine was exhibited at Windsor as a distributor of paraffin oil, which is known as a powerful insecticide. The nozzles employed distributed the paraffin upon the ground, and at fifty yards distance the spray could be seen like a delicate mist, following the machine. Blades of grass and leaves were picked up, coated by a fine film of paraffin, the odour of which would repel any insect pest. The machine is equally effective as a distributor of artificial fertilisers, such as nitrate of soda, or common salt, or with an insect-destroyer, such as powdered quicklime. It can be utilized for the sowing of seeds, and is applicable in a special form in hop gardens and vineyards. Finally it can be effectively applied as a sanitary apparatus, and it is to be hoped that Sir H. Harrison and his colleagues will soon be able to Strawsonize certain parts of Calcutta which it would be invidious to mention.

MORE ABOUT STRAWSON'S AIR-POWER DISTRIBUTOR. A VALUABLE INVENTION.

(From the "*North British Agriculturist*,")

Since Mr. Strawson's Air-Power Distributor was brought out last year too late for exhibition at the Royal Show, we have frequently referred to the immense value of this invention to farmers. By means of a powerful blast of air generated by gearing from the driving wheels, all kinds of grain and manure can be distributed in any degree of thickness over a given breadth of ground with mathematical precision. As a distributor of grain and manure the machine possesses many outstanding advantages, but its great value to farmers lies in the fact that it can distribute even the smallest possible amount of liquid or poisonous matter with unvarying regularity over any crop for protection against, or the destruction of, insect pests. A gallon of paraffin can by means of it be spread over a whole acre of turnips so evenly that every plant will receive its due share, and the effect of such a dressing is to effectually check the ravages of that dreaded pest—the turnip fly. By means of this machine, the farmer can effectually protect himself against those insect pests which attack his turnip plants, and fruit-growers can in the same way dispose of the pests, which attack their bushes and fruit trees. The merits of the machine were fully tested before a large gathering of practical agriculturists at the Royal farm at Windsor the other day, and aid its work to perfection. We now learn that a company of influential

agriculturists, headed by Mr. Jacob Wilson, has been formed to acquire and work Mr. Strawson's invention. Mr. Wilson is a gentleman on whose judgment the agriculturists of Great Britain have justly placed the most implicit confidence; and now that the invention has been taken up so enthusiastically by him, the destruction of turnip and fruit crops by insect pests will, doubtless, in a very short time be a thing of the past.

The Times, February 11th, 1889, says "It is very evident that, before long, 'Strawsonizing' a crop will be a recognized farm operation." In addition to applying insecticides, for which it was especially invented, it is the most perfect and rapid Distributor of all Corn and Seeds, Nitrate of Soda, Thomas' Phosphate, Salt, Soot, Lime, and other artificial fertilisers. For particulars apply to Strawson & Co., Newbury, Berks.

[An engraving shows a machine of the size of a big dogcart, drawn by one horse with a man sitting in front. No doubt it could be adapted for hand-power to suit plantation work.—Ed.]

TEA PLUCKING AND TEA PRICES.

Of course, in discussing the relative merits of any two systems of plucking, no rigid comparisons are possible, for circumstances differ so much on different estates. Indeed, we know the opinion is held by planters of experience that no "very fine" plucking is possible in hot, low-country districts, where in the forcing weather the flush almost runs away from the pluckers, and that if it were strictly carried out its affects upon the trees would be most detrimental. Without entering just at present upon this question, but dealing with the conditions which exist on the great majority of estates here, we find that it is quite possible for them to make a change in their present system of plucking—the question we have to consider being whether it will pay them to do so. Circumstances differ widely in different cases, and there are many estates at present realizing—in spite of the prevalent low prices—such excellent averages for their tea, as to put any change in their system of plucking out of the question. But, unfortunately, there are others—and we fear the majority—who find that present prices leave but a small margin of profit. We do not see, however, that they will be able to improve matters by plucking "fine," as is recommended to them by London brokers and others. The present price of Pekoe Souchong is low, but in our opinion, it is not likely to go much lower. Assuming however that it went down to 5d a lb., it does not follow that it would not pay to pluck it, for it reduces the cost of manipulation all round, and, moreover, generally speaking, it costs nothing to pluck. This seems very paradoxical, but it really is not so. For instance, a well-known planter recently divided a gang of fifty pluckers, and sent them into the same field, half having instructions to pluck fine and half to continue medium plucking as usual, and the following was the result:—

25 coolies brought in	311 lb. leaf
25 coolies brought in	198 "

113

Now, we may safely assume that these 113 lb. of leaf were Pekoe Souchong, and furthermore it is quite plain that the cost of plucking was nil! Supposing, therefore, that only 5d a lb. was realized for it, there would be a distinct profit on the leaf, for it would not cost more than 15 cents to manufacture. At first sight, no doubt, it is difficult to understand how there can be any profit on the Souchong of an invoice selling say at 7d., when the average cost of production is perhaps as high as 8d. or 8½d; but, as a matter of fact, all the profit there is, is earned by this low-class tea. If anyone differ from this opinion let him deduct the Souchong from an invoice and work out the tea remaining (Pekoe and Broken Pekoe) at a rate say 10 cents higher than his old average and see what the result is, allowing, of course, a slightly higher rate for the cost of production. Some figures have lately been shown us and placed

at our disposal by a merchant and large estate proprietor, which show the result of such a calculation very clearly, and thus provide an excellent comparison of the different results obtainable from fine and medium plucking. The figures as regards acreage, yield, and average price realized are not hypothetical, but taken from the returns of a young and promising estate at a medium elevation. Assuming that fine plucking reduces the intake of leaf 33 per cent; that the cost of laying down the smaller quantity of tea thus dealt with is raised from 30 cts.—which is the rate actually ruling on the estate referred to—to 35 cts.; and that the fine tea would realize an average 10 cts. higher than that hitherto obtained, the following result is obtained:—

MEDIUM PLUCKING.—200 acres at 300 lb. an acre.	
60,000 lb. tea @ 55 cts.	R35,000
Costing @ 30 cts.	R18,000
Profit	15,000
FINE PLUCKING.—200 acres at 200 lb. an acre.	
40,000 lb. tea @ 65 cts.	R26,000
Costing @ 35 cts.	RI4,000
Profit	12,000

Difference in favour of medium plucking 3,000

It may be said that the average estimated above, viz. 55 cents is high, and the cost of production, viz. 30 cents, is very low; but the figures are those which actually obtain on a certain estate and can be modified to suit the peculiar circumstances of anyone. It will be seen, however, that if we apply this formula to an estate obtaining a lower average for its teas, the result is much the same—only that there is a difference in degree. Not until the price realized approaches the cost of production does it really pay to pluck fine. There is, of course, an exception to this, mentioned by us yesterday. We allude, of course, to the case of a planter who has an insufficiency of space or machinery to deal efficiently and carefully with the large quantities of leaf coming in. In that case, of course, it would be better to pluck finer, and thus reduce the quantity of leaf manufactured. But such a case is, of course, exceptional, and our contention does not apply to it. It will be noted, in the comparison made above, that 10 cents per lb. has been allowed as the increase in price obtainable by manufacturing only the fine leaf, and it has been said by one to whom we showed the figures that as much as 12 cents ought to be estimated. We very much doubt, however, whether as great a difference as this good be calculated on throughout the year. Leaving, therefore, the cost of production, the yield per acre, and the proportion of the leaf the same, let us see how the calculation looks with the average price reduced, assuming always that a 10 cents better average could be obtained by fine plucking. The result is very instructive:—

MEDIUM PLUCKING.—200 acres at 300 lb. an acre	
60,000 lb. tea at 50 cts.	R30,000
Costing at 30 "...	18,000 R.
Profit ...	12,000
FINE PLUCKING.—200 acres at 200 lb. an acre.	
40,000 lb. tea at 60 cts....	R24,000
Costing at 30 "...	14,000
Profit ...	10,000

Difference in favour of medium plucking...2,000

MEDIUM PLUCKING.—200 acres at 300 lb. an acre.	
60,000 lb. at 45 cts. ...	R27,000
Costing 30 "...	18,000
Profit ...	9,000
FINE PLUCKING.—200 acres at 200 lb. an acre.	
40,000 lb. at 55 cts. ...	R22,000
Costing at 35 "...	14,000
Profit ...	8,000

Difference in favour of medium plucking...1,000

MEDIUM Plucking.—200 acres at 300 lb. an acre.	
60,000 lb. at 40 cts. ...	R24,000
Costing at 30 "...	18,000
Profit ...	6,000

FINE PLUCKING.—200 acres at 200 lb. an acre.			
40,000 lb. at 50 cts. ...	R20,000		
Costing at 35 „ ...	14,000		
Profit ...	6,000		

No difference between the two systems.

Now, at present exchange, 40 cents is about equivalent to 8½d. and low as tea has fallen it has not gone down to that yet, so that most estates must realize a better price than that rate; and yet, not until the average touches that figure will fine plucking leave the same margin of profit that medium plucking will do. Of course, many exceptions can be taken to the above calculations, but it is impossible to draw up a table that is not open to this objection; and if we have brought it home to our readers that, under ordinary conditions, fine plucking as a panacea for low prices is a snare and a delusion, we shall have accomplished all we have attempted. Whatever the average of an estate may be—provided that average price includes the rates paid for all grades, that is for Pekoe, Broken, Pekoe, Pekoe Souchong and cost—it will only pay to pluck fine, seemingly when the average closely approaches the cost of production. But it does not, of course, require mathematical demonstration, but is obvious on the face of it. The above calculations, however, considerably astonished us when we first examined the figures, and we should very much like to have the opinion of our readers on the matter.

There is yet another point of vital importance with which we have not dealt, namely, the effects upon the tree itself of a continuation of fine plucking. It is thought by many planters whose opinion is entitled to weight, that few estates could stand a prolonged system of fine plucking, and, if this be so, it would add another powerful argument to our contention, that medium plucking is the safest from a commercial as well as from an agricultural standpoint.—Local “Times.”

POTATO GROWING.—My friends in Western Victoria are always interested, I know, in anything relating to the cultivation of potatoes. Perhaps one of our most famous English scientific potato-growers is Dr. Gilbert, of Rothamsted. He has recently shown that there cannot be too liberal a supply of farm-yard manure, mixed with artificial. Perhaps the most important point he made is that the continuous growth of potatoes upon the same land does not render the crop more liable to disease, but actually the reverse, and this in spite of any fluctuations of the seasons. Of course this statement which is borne out by a large number of experiments tends to overthrow the idea that the potato disease is propagated by the existence of resting spores in the ground. At the same time Dr. Gilbert insists upon the importance of destroying all diseased tubers by fire.—*Dr. Taylor in “Australasian.”*

TIMBER DISEASES.—At the Royal Society conversazione, among the curiosities exhibited, were, says *Nature*, various parasitic fungi, by Prof. H. Marshall Ward. These specimens included: a piece of deal with grey mycelium of *Merulius lacrymans*, causing the common “dry rot” of timber; and a similar piece of timber attacked by the white mycelium of *Polyporus vaporarius*, another and quite different fungus, which produces a form of “dry rot;” portion of Pine-stem infected with *Peridermium pini*, the *Beidium* form of *Coleosporium senecionis*—the other form of this parasite is found on various species of Groundsel (it does much damage to the Pines in some forests, producing so-called “cankers” as disastrous as those of the “Larch disease”); specimen of Wheat infested by *Ustilago carbo* (*U. segetum*), showing the destruction of the ears by the fungus, the black spores of which completely occupy the interior of the grain; specimen of grass attacked by *Epichloa typhina*, a destructive ascomycetous fungus which infests the flowering shoots of pasture grasses; culture specimens of *Sclerotia* developed from species of *Botrytis*, which destroy certain garden plants. Microscopic preparations of these were also exhibited.

THE FACTORY for making sulphate of quinine in the cinchona plantations, Naduvatom, is now built, and working has commenced under the superintendence of Mr. Hooper, the Madras Government Quinologist.—*Madras Mail*, July 6th.

A SAFE METHOD OF TRANSPORTING SULPHURIC ACID.—Herr Bickmann has patented in Germany a process for embalming sulphuric acid for manufacturing purposes to be safely transported. He takes advantage of a property of certain salts—of which alkaline sulphates are representatives—by which they give up their water of crystallisation when heated and take it up again when cool; and he does so by mixing these salts in an anhydrous condition with a calculated quantity of sulphuric acid. The whole mass becomes granular, or may be formed into cakes; and when heated the whole liquefies and may be used as if it were sulphuric acid, for the presence of bisulphate of soda does no harm.—*Electrician*.

COFFEE UNDER SHADE: A NEW CLEARING.—For an interesting young clearing in coffee we are referred to Kondesalle estate in the Dumbara Valley, where 100 acres of old cultivated land, but which have been under lantana for 20 years, have been cleared and planted with coffee 5 by 5 feet, cacao 10 by 10 feet, and also at 10 by 10 feet, as shade for the coffee, with the *Ficus glomerata* (the shade tree used in Coorg and which is plentiful in Ceylon from 1,000 up to 5,000 feet—native name “attikka”). This clearing of young coffee flourishes exceedingly without a sign of fungus or bug so far; but, strange enough, plants taken from the same nursery and put out amongst old coffee as supplies, and more or less shaded by jak trees, are already covered with the leaf fungus. If the coffee in the young clearing keeps all right long enough even to give three or four decent crops, Mr. Hamlin considers his Company may be well satisfied; for they will then have the cacao well established to form their permanent plantation, that is should the coffee begin to fail after, say, the 6th or 7th year. This is a mode of planting which may well be recommended wherever there is soil deep and rich enough to carry cacao as well as coffee; but where the soil is too light for cacao, we should like to see coffee and the shade tree (*F. glomerata*) tried together after the Coorg fashion up to 3,000 feet or even higher wherever there is chena, or a bit of forest-land left.

MACE AND NUTMEGS.—The important spice market of Amsterdam is evidently coming under the control of a syndicate who are at present manipulating the stocks of nutmegs and mace, basing their operations on the small crop of November-December of last year. Messrs. Schroeter & Co., of Amsterdam, inform us that the “ring” is composed of speculators not directly associated with the trade who are operating through a Rotterdam firm. The syndicate, our informants tell us, appear to command abundant capital, and in that respect at least may be expected to make their venture a success, and may raise the prices of mace and nutmegs to an enormous figure. Supposing it to be a fact that the shipments for the second half of this year will be small, the Holland stock of nutmegs—which are specially preferred by the “ring”—will be quite sufficient for the world’s consumption for a whole year, and stocks have steadily increased since January last. On the other hand, there is only sufficient stock of mace for at most three months, as mace has suffered comparatively more from drought. But Messrs. Schroeter & Co. believe the short crop has been fully discounted by present high prices, and, according to latest advices from Banda, the trees are again in full blossom, and promise a good crop for this year. Under these circumstances it is doubtful whether the “ring” will find their operation pay in the end, and they are the less likely to succeed if consumers continue to buy for actual wants only.—*Chemist and Druggist*, June 22nd.

Correspondence.

To the Editor.

RICE CULTIVATION IN THE BATTICALOA DISTRICT.

8th June 1889.

DEAR SIR,—Mr. Edward Atherton has not, I think, given you all the reasons why paddy cultivation in the Batticaloa district does not always pay.

He does not tell you, for instance, that in very many cases the land has been purchased and brought into cultivation with borrowed money, and that the usual rate for such loans is 16½ per cent. That besides the money so borrowed the cultivator also, as a rule, borrows sufficient paddy to sow his land and for himself and his labourers to subsist upon until his crop has matured. And that for every bushel so borrowed he pays back at harvest-time one and a half bushel. (About 150 per cent per annum.)

Neither did he tell you that to speak of the cultivation of rice in that district is a misnomer. All that is done is that the well-turfed surface of a fallow field is scratched with a plough and trodden by buffaloes. The fields are not even levelled. It is highly probable that if they were as carefully cultivated as (say) those between Peradeniya and Gampola, the crops would be at least double what they now are.—Yours truly,

O. W. K.

KEEPING QUALITIES OF CHINA TEA.

37, Mincing Lane, 21st June 1889.

DEAR SIR,—To the Ceylon Planter who by each mail receives some complaint as to the keeping qualities of Ceylon tea, the accounts of the advantages China tea possesses in this direction must seem incredible.

Thinking it may interest you we post you a tasting of a fine China tea, "Kintuck," recently sold on this market. The year of importation was 1882. You will find on examination that the leaf is comparatively crisp, the infusion bright, and the cup strong and flavory after seven years in the warehouse.—Yours faithfully,

I. A. RUCKER & BENCRAFT,
p. W. B. CHALMERS.

[The tea looks in very good order certainly and is every way satisfactory.—ED.]

PROGRESS IN THE STRAITS SETTLEMENTS.

30th June 1889.

SIR,—It may perhaps be of interest to some your readers to hear how, under the able and progressive administration of Sir Cecil Smith, railway extension is being pushed forward in the native states of the Straits Settlements.

At present there are two lines already completed, viz. that from Port Weld to Thaipang in Upper Perak and from Klang to Kwala Lumpur in Selangor: this latter is immediately to be extended to Rowang, and another line some 35 miles in length is under construction in Sungai Ujong. It is not however to these lines that I particularly wish to refer, but to that which has now been sanctioned by the Secretary of State, from Teluk Anson to T'poh, a distance of 62 miles which is undoubtedly the first link in a chain of railway communication that must, before many years have passed, connect Singapore with Burmah. Teluk Anson, the present terminus of the Perak railway, is situated 35 miles up the river of the same name which has a depth of 16 feet at low and 22 feet at high water. The sanctioned line of railway will run in a north-

easterly direction through a splendid country for agricultural purpose, to Tappah, which will form the first section and which will probably be commenced before this year is out. From Tappah the railway will be continued on to T'poh, a distance of about 30 miles, through a country abounding in minerals and in which there are already very extensive mining operations in progress. It is I believe under consideration if the line shall not be extended to the Dindings or to Penang, but the trunk line will undoubtedly be pushed on to Moulmein. A further extension is to be undertaken that is to run from Tappah to Tanjong Malim, to the southward, for about 35 miles. At Tanjong Malim the Perak railway will join that of Selangore, and that line will be sooner or later brought into communication with Singapore.

W. A. M. D.

GRAIN CULTIVATION IN THE EASTERN PROVINCE.

Batticaloa, 1st July 1889.

DEAR SIR,—Mr. Elliott has drawn a 'nest of hornets' about his ears by attempting to prove how paddy could be successfully cultivated with a profit of 70 per cent.

Another friend with the same tendencies for agricultural proficiency proved how he had made finer results, by sowing a few grains in a highly manured flowerpot without incurring any cost whatsoever, and we have Bishop Chapman's assurance (vide his published journal) how he saw paddy growing on one side of him, and rice on the other, in this district.

These facts, though interesting, will not bear analyzing.

I am only surprised that an officer of Mr. Elliott's experience should allow such a document to go before the Government and the public, without strict inquiry whether the facts and figures stated therein are correct. We all know the tendency agricultural students have, of showing great results at little cost; and I assert, without fear of contradiction, that 70 per cent could not be obtained by any mode of cultivation from the ordinary land of this district, except by heavy manuring and 'Rajakariya' services, which latter, Mr. Elliott's return savours of!

Where are the rich proprietors who once farmed the lands in this district, whose possessions in land and cattle could not be enumerated 'ruined'—'beggared'—'dead'! Men who to my knowledge had several years' paddy stacked, for the consumption of their field labourers. What ruined them? Surely not the 70 per cent returns; but excessive commutations added to water cess, that crying evil, which has ruined the district and alienated extensive tracts from their original owners, now lying waste and uncultivated.

The Kachcheri records will prove, what extent by this means has reverted to the Crown.

I shall give one instance, as an example,—Attee Munmari, in Manmunai Pattu North, of 134 acres extent. The commutation of this field is assessed at R196-56. The highest rent yet obtained is 15 ammunams of paddy worth R112-50, so that for the "honour and glory" of having this cultivated, the owner has to pay Government R84 in excess of the rent! If paddy cultivation is so profitable, how is it that the rent is so low? lower than the tax—the ordinary rent being equal to ½ of the crop, or double the commutation tax.

The inference can easily be drawn, and we know the object with which the statement has been furnished, to drown the general outcry, and to quiet the conscience of "the powers that be"—to avoid a Commission that would necessarily elicit the truth!

The fact is quite patent. By increasing the commutation suddenly from R600,000 to R900,000, the natural food of the people has been raised 50 per cent! What a sensation this would cause, if brought before the British Parliament?

I am a cultivator, possess lands in this district and can from experience state that the figure, given in Mr. Elliott's return are considerably below the actual rates. For ploughing 7 acres—with the improved plough especially—2 pair of cattle will be required:—

	Amunams.	Markkals.	Equal to	Bushels.	Pecks.
Hire, 2 pair cattle.....	1	1	22	14	
Seed	1	1	22	14	
Consumption paddy a man and boy	15	15	33	21	
Plough and mammoth	15	15	33	21	
Threshing by night 4 pair cattle ..	1	1	4	1	
Hire of 2 coolies.....	1	20	12	14	
Reaping.....	1	20	12	14	
Fee to V. Vidahana and Adigari...	1	6	1	12	
	13	28	104	14	

Average yield of 7 acres equivalent to 3 amunams extent at 7 fold as shown below:—

	Amunams.	Markkals.	Equal to	Bushels.	Pecks.
Yield 7 acres.....	21	1	157	14	
Expenses	A. 13	M. 28	B. 104	P. 14	
Tax	2	3	15	21	
Leaving.....	4	29	37	7	
Landlord's share	2	3	15	21	
Cultivators' share, men and boy...	2	26	21	14	

In other words, the landlord for all his outlay and trouble gets only R15-75 for the cultivation of his field—an amount equivalent to the Government tax! Where does the boasted 70 per cent come from? The clouds? or the vivid imagination of the writer?—I am, dear sir, yours faithfully,
EDWARD N. ATHERTON.

COTTON CULTIVATION IN CEYLON: PRACTICAL EXPERIENCE.

3rd July 1889.

SIR,—It is a little unfortunate that discussion about our new industry cotton has so soon resolved itself into an exhibition of personalities and smart writing. Let us know a little more about the climate of cotton-growing countries, and then point out which districts in Ceylon are likely to be most suitable for its cultivation. We all know now that cotton of one kind or another will grow all over Ceylon from the seaborde to 4,000 feet in Ramboda, and 5,000 feet in Uva, but we want to know where it can be grown with a fair chance of profit, in absence of any unusual climatic disturbances, that is unusual to that location.

Many of us have had experience enough to prove the capability of Ceylon growing cotton. I have had kidney-cotton growing below Cannavarella. It never attained any great size, and very often a spell of showery weather spoilt the pods when ripe. I have grown the same cotton at the bottom of the Pundaluoya valley, hot and wet, say 3,000 feet in elevation. There the trees grew to a diameter of 3 to 4 inches in the stem, and 10 feet high lasting for years. The pods ripened at all times of the year, sometimes spoilt by rain, sometimes yielding cotton in good order, and very often with the pods full of little beetles of kinds. I should

think that cotton-growing as an investment would not be likely to turn out a success in either of these districts; and from what I know of the climate of the Central and Uva Provinces I should very much doubt if any part of them would be safe for such a venture, unless it were Udakinda and at the foot of the Haputale and Namunakulu ranges in the lowcountry.

Many years ago we used to be told that when the rainfall in the cool districts of India failed to suffice for paddy cultivation, cotton was put in the fields instead; and from all I can learn the main characteristic of the climate of Tinnevely and the cotton districts of Southern India, as well as around Ahmednugger, farther north, is a short spell, say three months, of showery weather, followed by a rainless period of six or eight months, during which the cotton pods ripen and can be harvested without fear of damage. If this is what we want we must leave the hill-country of Ceylon and go down to Dambulla and Kaluwewa, and take up the flat rich soil so much talked of in the lowcountry. I don't pretend to have any experience of that locality, but from all I have heard the soil and climate must be very similar to that around Wellawaya and Tissamaharama and Jaela, which I have visited in the course of my travels. Again below Rakwana, at Maduwanwella and the irrigation works to which so much attention has been drawn lately, I may mention that Maduwanwella has several kinds of cotton growing at the famous walawwa. I have no wish to make a positive statement, but I think that the cultivation of cotton in the uncertain climate of the Central, Uva, and Western Provinces would be always very precarious and consequently unprofitable. What we want is experience on a pretty large scale in the lowcountry, north of Matale, at Anuradhapura and Kalawewa.

How is it that all this time no one has come forward with accounts of the results of the cotton totem at Chilaw or Puttalam belonging to the late J. Home, who used to walk about the Fort in a suit of his own growth and manufacture? He imported weavers from India and had his cotton woven into cloth. Am I wrong in supposing that Mr. Kemlo was the superintendent in charge, and that he is still in the island? Can't he be induced to tell us something about it, cost of production, &c., &c.?

I may add that the difference in climate between the coffee districts of Ceylon and those of Mysore fully accounts for the advantage of planting under shade in the latter, and the disadvantage in the former. In comparing notes lately with a planter from Mysore we mutually arrived at this conclusion. In Ceylon we cannot fully realize the fact that obtains over so great a portion of India. No rain whatever for half the year and more.—Yours faithfully,

EDMUND WOODHOUSE.

[But Mr. W. A. Tytler, who has had experience of both, considers a great part of Uva to approximate very closely to the Mysore coffee districts in climate and soil.—Ed. T.]

CINCHONA BARK IN INDIA AND CEYLON: HOW TO REGULATE THE HARVESTING AND EXPORT.

SIR,—I have no doubt there are still planters in Ceylon vitally interested in cinchona. There are certainly such in India and Java, and with the drest low unit rain stares them in the face. Nor is there any hope of the unit rising unless the amount of bark put into the market is greatly diminished.

I believe that this can be done. Not at once perhaps, but, by a cordial co-operation of planters, in six months' time. And who so ready, who so

able to attain this co-operation as you planters, who already have their Association to work through? That is to say when once it has been thoroughly, and in this case cruelly, brought home to them that their only remedy lies in such co-operation. Left alone, the planter, and I am sorry to say not only the cinchona planter, becomes a sort of bullock doing his daily round (I know this from my own experience), taking his bark and cropping his coffee without reference to the state of the market, and later on lamenting either the small balance of profit or the loss. In this case too, the co-operation would only extend to a few hundred planters and to the produce of some few millions of lb. It would also, I am almost certain, receive the cordial support of merchants, brokers and even purchasers of bark, for everybody will benefit by a rise in prices. Not the consumer of quinine you will say, but judging by druggists' prices he would not benefit even if the unit were to go to a halfpenny; and the consumer must help himself. For us producers, charity begins at home.

Now I would point out to all bark producers, and they will readily assent once it is insisted upon, that at a double of the present unit half their bark will be of greater value to them than the whole of their bark at the present unit.

Let us take a lb. of bark, analysing 3 per cent at the present unit: this would fetch 3½d or presumably only 3d. Now supposing the unit were at 3d, half a lb. of this bark would fetch 5½d. Again, take the cost of putting into the market at 2d per lb. (I am working on my own figures): then on the one lb. of the bark at the present unit, 1½d is netted, while a profit of 3½d would accrue from the ½lb. at a 3d unit. Work this up or down according to analysis and it will come to nearly the same result: if anything it is in favour of lower analysis which prevail in Ceylon and parts of India.

Now, I am certain that, if half the amount of bark now put into the market were shipped from Ceylon, Java and India, a 3d unit would be the result, perhaps not immediately, but not long in coming.

Besides the present leaden tone of the market would give place to one of elasticity and speculation, both good for the producers. I am even sanguine as to not a 3d but a sixpenny unit, and mercantile authorities would, I am sure, bear me out in this.

South America we may leave out of the question, for I doubt whether large amounts of uncultivated bark could be into the market even at a six penny unit. For the trade in uncultivated bark must of late years have been so disorganized, that it would take time—and money to reorganize it.

I have tried to show how, if only half the present bark were put into the market, it would inevitably benefit the producer. Now as to how this might be accomplished. Fortunately we have, as I have said, powerful "Planters' Associations" to help us, and we have planters' "esprit de corps," and it is to the latter that I would specially appeal, for I know how great it is among planters. There is a Planters' Association in Java too, and I think the present unit will find them ready to aid in cordial co-operation. It would necessitate then a co-operation between all the Planters' Associations of those districts of Ceylon, Java and India, in which cinchona is cultivated, and a unanimous resolution that only half the amount of bark estimated as crop produce should be cropped and shipped. The word of planters should be taken in this case; and should they only be managers, they could easily point out to their employers the advantages accruing and get their sanction. There would always of course be a few black sheep who would send in the whole of their bark on a rise of the unit. But being a

planter myself, I believe their number would be limited, and even of that number a great many would be prevented by fear of Association censure. In the first place communication would have to take place between Associations, and, if success be deemed possible, negotiations between their executive members and other members would have to be opened and the results transmitted to some central Secretary of Association decided upon. This would have to be done in Ceylon and India to begin with, and then communications would have to be entered upon with Java. It might even be possible that a special mission to Java would be necessary, but if a unanimity were arrived at between Indian and Ceylon cinchona producers, no difficulty ought to arise in finding the funds for such a mission. And the fact, that such an agreement had been entered into by Ceylon and Indian cinchona planters, would make an adhesion of the Java planters very nearly certain, if it were pointed out to them, that a final decision on the campaign depended on their hearty co-operation. The matter requires a start; but as soon as that is made, and with a little pluck, I believe it will lead to success. Being largely interested in cinchona estates I am trying to make that start. I shall be very glad to receive any communications from the various (if such there be) Planters' Associations in Ceylon, and, through the Planters' Associations in India, do my best to further the cause. For this purpose, I subjoin my full name and address.

Will you allow me to further state, that, although very greatly interested in this question, I am not trying to work for myself only. My bark analyses 3 to 3½ per cent original and 5 to 6½ per cent renewed. So I could well wait until the rush of bark at unprofitable prices had passed. But meanwhile many another who is only getting 2½ per cent all round is going to the wall. In conclusion, I may say that estimates of full crops, and therefore half crops to be put into the market, should be arrived at by the Associations and that the latter should, as bodies of honorable men, guarantee the same, by whatever means they got their facts.

I would add, that the term of such co-operation could not be indefinite, and think that two years from date of the general agreement should be fixed as a limit. I am certain that this term would be sufficient to right the market.—I am, sir, yours truly,

G. ROSENBERG.

[Address:—Baron C. G. M. von Rosenberg, Devicolom, Madras Presidency, Southern India.]

COFFEE BUG (SCALE) AND THE TREATMENT BY KEROSENE AND SOAP EMULSION.

Calcutta, 2nd July 1889.

SIR,—I have read with much interest Messrs. Green and Jackson's letters, that have lately appeared in your valuable journal, upon the subject of the destruction of Coffee Scale by Kerosene and Soap emulsion.

The results of Mr. Jackson's experiments, conducted as they have been over so considerable an area, are most encouraging; and the fact that he has found that it pays to keep down the scale bug over 287* acres of coffee, by so tedious a method of application as that of rubbing over the affected parts of each plant with a piece of cloth soaked in the emulsion, shows, I think conclusively, that with modern apparatus for applying the emulsion, the complete success of the treatment is no longer a matter of doubt.

* Mr. Cotes will have seen that the acreage treated was not so great, according to Mr. Jackson's explanation in a second letter; but that does not affect the argument.—Ed.

Experience in Florida, in destroying an allied scale insect with kerosene emulsion, has shown that by far the most effective method of applying the emulsion is by spraying it in a cloud of fine spray, by means of force pumps which obviously must immensely reduce the labour: the object of the application being completely attained when the insects are killed, even though the dead scales remain upon the plant. Out of a total cost of about ten rupees per acre, over the 287 acres of coffee treated by Mr. Jackson, he estimates the actual cost of the emulsion at only about eight annas per acre, the cost of labour is therefore by far the heaviest item, and this will obviously be reduced by the use of force pumps; which have the further advantage of greatly facilitating the intimate mixture of the soap solution with the kerosene, a most difficult operation to perform completely by hand, and one that is absolutely essential for the efficacy of the application. It should be observed, in spraying the insecticide, that the nozzle must be such as to give a cloud of fine spray: this being most important, not only because the same amount of emulsion goes much further when sprayed in a cloud, than when sprinkled in drops, but also because a cloud of fine spray is found to be far more effective, than even a heavy drenching, in destroying the pest; the supposed reason being that the particles of fine spray adhere, and the whole of the mixture is thus utilized, while the large drops rapidly run off carrying most of the kerosene with them and leaving little but water behind upon the plant. The eggs of the scale insects offer much more resistance to the wash, than do the larval and adult forms. It has been found therefore that two light sprayings, with a short interval of time between them, are far more effective than a single though much heavier treatment, for the first application kills the adult scale insects and larvæ and the second application kills any larvæ that subsequently emerge from eggs which have survived the first application. In this connection it is important to ascertain, both the time that the eggs take to hatch, and also the time required by the young larvæ to arrive at that stage in their growth when they are able themselves to lay eggs; for the interval of time between the first and second sprayings should be sufficient to allow all the eggs to hatch out, without being long enough to permit any larvæ, that emerged after the first application, to lay eggs which might survive the second application.

I have written to Mr. Green to ask if he will consent to experiment with and report upon a force pump and cyclone nozzles, which have been sent to the Indian Museum for experiment, by one of the American firms that manufacture the insecticide apparatus recommended by the United States Entomologists; and in the event of his finding himself unable to undertake the experiments I shall be happy to hear of any other gentleman who takes an interest in the subject and who would consent to help; for I believe it is only by careful experiments with approved apparatus that reliable conclusions can be formed.—Yours faithfully,

E. C. COTES,
Indian Museum, Calcutta.

PRACTICAL QUESTIONS IN TEA CULTURE AND PREPARATION.

July 9th, 1889.

DEAR SIR,—As there are so many answers to the questions on "tea culture and preparation," it will be a very good thing if answers are given to some other questions on pruning, plucking, withering and firing:—

This is what Mr. Armstrong in his paper on the manufacture of tea read before the Maskeliya Planters' Association, Saturday, 29th August 1885, says:—"A strong healthy flush, resulting in heavy pluckings, will give the best tea."

- (1) When is it best to prune and how?
- (2) How should tea be plucked from the first picking after pruning till the end of the season?
- (3) About what percentage should be lost in withering to get what is called a "good wither?"
- (4) Should tea be fired till quite crisp or not; and should the teas be sifted while firing, so as to get all leaf equally fired?

I was led to put the first question, as Mr. Armstrong in his letter dated 8th May 1889 says:—"Pruning, *when and how done*, affects liquor more, perhaps, than some people imagine." The second is the most important, as by bad picking at the commencement, the teas cease flushing soon. These are notes I have on plucking:—

- (1) After severe pruning, when six leaves have formed take the bud only for 2 flushes, then for two more 2½ leaves (bud counted as one leaf), after this pluck as usual.—(*Money*.)
- (2) The first shoots should be allowed to grow 6 to 8 inches with 7 to 10 leaves each, pick bud and 2 leaves only.—(*Neilgherry tea planter*.)
- (3) After plucking for 3 rounds, 5 to 6 inches of primary shoots above pruning level, should be left, or 3 full leaves; perhaps more after a heavy pruning; after 3rd round all primary shoots may be plucked—on secondary shoots, it is at first well to leave 2½ leaves, including the bud leaf.—(*Taylor*.)
- (4) In former years the rule observed as close as practicable was to commence upon a six-leaf flush, taking 3 leaves and leaving 3, from the axils of which hitherto the 2nd flush come; when the 2nd flush attained 5 leaves to take 3 and leave 2; the 3rd flush proceeding from these in turn was often taken in the same way in the 4th flush. As soon as it attained 4 leaves it was usual to leave only one leaf on the bush. After the 5th and 6th flushes it was generally a clean sweep of everything that came out. The wood thus attained would probably at an average of 2 inches give a height for 6 flushes of 12 inches, which was considered sufficient to prune upon or rather to prune off; for it was as a rule cut off 3 inches above the former year's pruning, so that so much was wasted that might have been made into tea.—(*Indian Planters' Gazette*.)
- (5) At the beginning of the season instead of plucking upon a six-leaf flush, the flush is allowed to grow out to 8 or 9 leaves, when 3 leaves are taken off and the other 5 or 6 leaves left on the bush are allowed to remain and ripen into material for next season's pruning. After this first flush is thoroughly established, the garden is regularly visited by the women once a week and the bush is completely stripped of all new leaf which has shown during that time. At the beginning of the season if the growth is vigorous, leaving 6 leaves on a bush means at least 9 inches in height from the place where the shoot strikes out to the top of it, so that if we allow 3 to 4 inches above the former year's pruning, there still remains 6 inches of wood to be cut away. Another contention in favour of this system is that, allowing the flush to run this way in the beginning of the season, gives much cleaner wood, and that although on the very surface; there is before the end of the season a lot of brushwood, towards the end of the season the harder the bushes are plucked the harder they throw out? (*Indian Planter's Gazette*.)

Withering everyone allows is a very important matter, but what amount of moisture should be

lost.—The "Planting Molesworth" says:—100 lb. leaf should wither down to 75 lb. which should give 25 lb. tea. Rutherford's Planting Manual 100 lb. should wither down to 67 lb. In the *Indian Planter's Gazette*, taken in *T. A.*, August 1887, it says:—*Be careful not to over wither; better to be a little under done.* In the latter case you lose a few tips and get some broken tea, but you save the liquor, while in the former case all the strength has gone and you get a hard dry brassy liquor.

On Firing this is what different people say:—

(1) Keep the tea over these fires (choolas) until thoroughly fired, *i. e.* until all the moisture is completely expelled and the tea is perfectly dry and crisp.—(See *Planters' Gazette*).

(2) When teas are properly fired they should feel crisp to the touch and when bent resume their shape.

(3) Mr. Gepp before the P. A. at either Dikoya, Dimbula, or Maskeliya, said:—Tea should be fired till they have a taste of fire, but not burnt.

(4) Messrs. Wilson, Smthett & Co. in one of their circulars say:—The great fault in Ceylon manufacture is that the tea is too much fired and quite unlike the best China teas which feel quite spongy to the touch.

Should tea be sifted while being fired? This is always done when firing over choolas, and why should it not be done when firing in siroccos, as it stands to reason, that if the tea is taken out when the small leaf is sufficiently fired the large leaf will be insufficiently done, and *vice versa*.

If as many persons answer these questions as the previous ones, all the letters should be printed in pamphlet form and should command a ready sale, and these letters from people living under such different climates, with regard to rainfall, altitude, will be far more valuable than any work on tea planting and manufacture, ever published before. At present a man, say, lives in the lowcountry and is sent to a high district, he will fail if he tries the same style of plucking in one as he did in the other, &c. B.

TEA YIELD ON OLD LANDS: PRACTICAL QUESTIONS.

Colombo, 15th July 1889.

DEAR SIR,—All interested in the cultivation of the staple product of the island are deeply grateful to the many gentlemen who gave their opinions in answer to the three questions put by one of themselves with reference to the culture of tea. The kindly manner in which they replied, leads me to hope for further information, in the form of answers to the following questions with reference to tea planted in old coffee lands:—

1st. What do you consider the average age of the tea from which first pluckings have been taken?

2nd. What do you consider the average increase during the second year's plucking over that of the first year's?

3rd. What is the average increase of the 3rd year's plucking over that of the 2nd year's yield?

4th. What is the average increase of the 4th year's plucking over that of the 3rd year's yield?

5th. What is the average increase of the 5th year's plucking over that of the 4th year's yield.

6th. At what age do you consider tea in such lands in full bearing?

I do not ask these questions out of mere curiosity, but from a sincere desire for information, as the question has arisen whether tea at the present prices can be grown on old coffee lands to pay, and the answers to these questions might materially aid those who may have grave doubts as to whether it is wise to persist in the cultivation of tea which apparently takes much longer time to come into bearing than was contemplated.—Yours truly, W.

P. S.—The answers, if any of your friends will kindly reply might take the following form:—
1st crop from 2½ to 3 years from planting,

was equal to say 1,000 lb

2nd	„	4 years old	„	„	3,000 lb or 300 p.c. advance
3rd	„	5	„	„	4,000 lb or 33½ „
4th	„	6	„	„	6,000 lb or 50 „
5th	„	7	„	„	7,500 lb or 25 „
6th					
7th					

It is not necessary to give the exact crops so long as the proportions between the years are maintained.—W.

THE GOOD FROM AGRI-HORTICULTURAL SHOWS is well though only partially described by a Matara correspondent to the "Examiner" as follows:—

"Progress in agriculture or trade stimulated only by such small prizes as these Shows can afford to offer, must necessarily at first be slow. If they can only be continued till the exhibitors realized that the actual prize they may gain is but a fractional part of the reward that their industry or skill will secure for them, in a very few years the rate of progression being geometrical, will be very evident. Neither your space nor patience would allow me to enter into detail in proving that good results are being secured, so I will merely give instances of one or two facts which indicate an appreciation of the benefits gained by getting a prize at a Show. Should you come as a visitor to the district and wish to buy curious of local manufacture, the Rest House Keeper will probably mention 'Matara baskets,' and of the old women who produced them for inspection the one who can dangle before your eyes the 'Certificate of award' granted her at the last Exhibition, will stand in silence and treat with the supreme contempt of superiority the clamour of her less fortunate competitors. Should, however, you be of a more utilitarian disposition and require mats, matting, or lace, the manufacturers will take an honest pride in showing you either the Silver Medal or the Certificate which their skill and industry have gained them. Or, again, should you be commercially inclined and visit the traders in Citronella and Coconut Oils, you will certainly be told by the holder of last year's medal of the purity and superiority of his oil—qualities for which his medal is some sort of guarantee, which he has been 'cute enough to realise and will probably make you pay something extra for."

COFFEE LEAF DISEASE.—In the *Indische Mercur* of 22nd June Mr. van Gorkom, the former director of the Government cinchona plantations in Java, writes on the subject of Dr. Burck's recent inquiries into the cause and treatment of coffee leaf disease. We learn that Dr. Burck, noticing that in Java (as in Ceylon) the disease was virulent in the west monsoon, while during the dry weather it practically disappeared, came to the conclusion that the spores of *hemiteia* needed an abundance of moisture in order to develop; and after many experiments he recommends the following in the way of prevention or cure, viz. the formation of high thick belts of trees on the western side of plantations which will check the spores carried by the wind; the watering of plants in the nurseries with tobacco water and the surrounding of them with high belts of trees; and the removal of diseased portions of leaves by means of an instrument which he has invented (this superseding his former plan of pricking the infected leaves with a needle dipped in sulphuric acid). The conditions under which the spores germinate are said by Dr. Burck to be—water in fluid form, oxygen, and more or less complete darkness. The effect of the sunlight is to kill the spores by depriving them of water. We believe that a detailed report by Dr. Burck on his experiments is to appear shortly.

COCONUT LEAF DISEASE.

We direct attention to our Veyangoda correspondent's interesting letter on this subject, covering one from Dr. Trimen. It will be remembered that the scaly blight which attacked coconut plantations in Jamaica was also referred to in nutrition due to prolonged droughts. It is suggestive that the spots on the leaves, to which attention is now drawn, showed themselves after two successive droughts which could not but have enfeebled the trees very considerably. Whether the spots are to be regarded as anything serious or not, it is impossible to say without fuller knowledge of their true cause. Dr. Trimen's theory is only a suggestion, and will have to be verified by fuller inquiry than he has been able to undertake. It is to be hoped he will be able to find time and opportunity for the task on his return from Anuradhapura. If the spots merely tell a tale of undeveloped leaves, due to innutrition, or leaves attacked by bug owing to their weakly state, they will chiefly be found on those leaves which were being formed when the tree was in an enfeebled condition. Their absence from leaves already formed, or from fronds which were produced after the tree had recovered some of its lost vitality, will not be fatal to Dr. Trimen's suggestion. In this view, it would be important to note whether the leaves affected are more or less of the same age. We presume that, even if the leaves did not show the spots when first unfolded, they would, if weakly, be scorched in portions by the sun. Again, although weakly plants would more naturally show the spots than hardier ones, some of the former may have suffered less from innutrition at the particular time through the constituents of the soil in which they grow. Until the nature of the disease is ascertained, it would not be possible to prescribe any rational treatment. If the conjecture of innutrition be correct, fumigation, generally useful in dealing with fungoid and insect pests, could hardly confer any benefit. A fungus has, however, been traced on the leaves; and although it is asserted to be an effect, and not a cause, of the spots, we have no information of its character and whether it can be seriously hurtful to a plant or not. In the meantime, it would be well to watch the effect of fumigation on it, with sulphur or tar. Although there is not much probability of it, even the fumes from burnt coconut shells may be injurious to the fungus. Topical applications are often useless in dealing with certain disorders traceable to organic or constitutional causes; but in dealing with fungi with dangerous powers of reproduction, attempts to destroy them may well go hand in hand with examination of the soil and the roots of affected trees, and the adoption of means to invigorate them. A visit from Dr. Trimen to an affected estate should be arranged for at an early date: and we hope he may be able to dispel all cause for alarm in respect of a product which, like the British flag has braved a thousand years the battle and the breeze without mishap.—"Local Examiner."

SIROCCOS VERSUS CHULAS.

We have no intention of entering upon the question of the causes, many or few, which are believed to operate on the quality of machine-made tea, though it may be as well to remember that China tea which has of late years shewn such marked deterioration, is entirely hand-made.

We wish, however, to remark on an opinion we have seen in print in an Indian planting paper, to the effect that the decline in quality of British grown tea is due to the employment of Siroccos, and that the only safe course to pursue is to revert to the use of hand firing by means of the native "chulas" over charcoal fires. It is declared that in the olden time tea thus fired was rarely, if ever, over-fired, and was of far more even and more lasting quality.

We suppose there can be no doubt that to fall back upon the old system of firing would now be impracticable, if only on account of the impossibility of procuring a sufficient number of labourers, to say nothing of the much larger space that would be required in the

factory. Those who lay so much emphasis on this alleged defect in the modern system of tea drying by machinery, point to the fact of most of the older tea estates in Ceylon realising generally higher values for their leaf than is obtained by comparatively new places; and this is explained by them as showing that with heavier crops the leaf has to be forced through the drier at a higher temperature than formerly, in order to keep ahead of the work, hence over-fired tea, which is said to be the cause of decline in quality.

It appears to us that were this argument sustained, and the conclusion granted, it would not follow that Siroccos should be abandoned, but that the remedy should be found in a larger supply of drying power, additional Siroccos, so that there need be no occasion to force leaf rapidly through a drier at a higher temperature than is safe for the good quality of the tea. We think our readers will be inclined to adopt this view, always supposing the facts to be as stated—that this over-firing is at the root of recent complaints regarding the quality of Ceylon tea.—*Ceylon Advertiser.*

COCA CHEWING.

Practical science should certainly have set at rest by this time whether the chewing of "coca," as practised by natives in South America, increases the chewer's strength and powers of endurance. This has been alleged and denied over and over again, and with all possible emphasis on both sides. But the testimony just given by a resident in Warwickshire carries the matter a little farther because he speaks from personal knowledge. For 13 years he lived on the slopes of the Andes, and while there he came to the knowledge of very wonderful athletic feats which were apparently due to the consumption of coca. Native porters think nothing of carrying burdens of from two to three cwt. for 50 or 100 miles at a stretch, provided they are supplied with a due allowance of the miraculously sustaining leaves. In the same way, the native miner will go on toiling for 30 hours in succession with no other food. And so on; a long list of physical achievements not to be paralleled on this side of the Atlantic. It is quite possible, nevertheless, that coca does not possess the miraculous qualities attributed to it. The natives are trained, it is admitted, from the earliest youth to carry heavy weights long distances on little or no food. And long training is a wonderful thing for bringing out the latent possibilities of human strength. Look at the long distance cyclist who will go wheeling along for 24 hours at a stretch, at an average speed of 11 or even 12 miles an hour. Throughout the time, he takes no rest whatever, while his nutriment is about sufficient to serve for an ordinary breakfast. Yet his training is probably only of recent date, whereas these South American coca eaters have had their muscles hardened and their appetites restricted throughout their lives. Perhaps some of the Catford Club riders will give the leaves a trial.—*Globe.*

"ALL BOUT TEA."

Messrs. Rucker & Bencraft at the suggestion of friends in Ceylon have prepared and published what they call "a Ceylon Supplement" which they have widely distributed in the island by this mail. It contains a good deal of useful information to planters although most of it has appeared before and will be found embodied in our *Tropical Agriculturist*. They begin with the "Dealer's Ultimatum," as to gross and tare and average net weights. Nearly every firm of note has publicly declared they will "boycott" untared packages. So far back as November 1885, and again in August 1887,

Rucker & Bencraft gave suggestions how to get over the difficulty of varying tares, and revised Customs Regulations were also published in Nov. 1885. On this subject the "Supplement" says:—

By these rules the Customs took upon themselves the power of allowing a margin of two pounds upon the Gross weight, and getting an average Net by turning out and taring 10 per cent of a break. The experience of the Dealers who have signed the before quoted circular, is that in practice, 75 per cent. of the weights are against them in parcels so treated. Complaints have been rife in the country about loss in weight, and now the country grocers and dealers have refused point blank to buy from the London Trade any more Ceylon and Indian Teas, unless with an average tare, instead of being "weighed net," as it is termed. This compels the London Dealers to "pass it on" to the Merchant, who has now to face the position. Either he must manage to get his packages to tare even weights or each package will have to be Bulk and tared here as we pointed out in the circular of November 25th, 1885.

The Japan packages have this advantage, that the weight is very even, but as we said before, take great care that the wood is well seasoned, and suitable for tea. Until the lead of a Japan package is cut, or even for a few days after cutting open for inspection the tea will remain all right, but after being sold for a month or two, if the wood is the least aromatic or cedary, the scent is certain to affect the tea, and then up comes the package from the country buyer with the complaint the tea is unsaleable. The London dealer pockets the loss and says nothing, but become prejudiced against what ought to be, and are if carefully chosen, most useful and well made packages. The Stanley Wrightson packages run even tares also, and possess many other advantages. The perfect package is not yet made.

Then follows a table:—

Per Package weighing Gross.		160 lb.	130 lb.	90 lb.	80 lb.	80 lb.	60 lb.	45 lb.	35 lb.	17 lb.	Not
		to	to	to	to	to	to	to	to	to	exceeding
		199 lb.	159 lb.	129 lb.	89 lb.	89 lb.	79 lb.	59 lb.	44 lb.	34 lb.	16 lb.

The above Weights are chargeable on the average gross weight of each break. When the fraction of the average weight is half-a-pound or more, the higher rate will be apply. Thus:—The average of a break being 79½ lb. gross, the whole break will be rated at 80 to 89 lb., but the average being less than 79½ lb., the whole break will be rated at 60 to 79 lb.

(N.B.—5d per package for a difference of half a pound.—I. A. R. & B.)

SALT IN COCONUT CULTIVATION.

My object in writing this is to correct a misapprehension of yours as to the views I hold on the use of salt in combating leaf disease. In crediting me with being "confident that salt will be of use in combating and averting" leaf disease, you unconsciously do me an injustice. All I did was to propound a theory that, as in cultivating Coconuts inland, the natural conditions under which they grew were absent, disease followed. I proposed applying salt freely as a top-dressing to Coconut properties in inland districts, so as to reduce the dissimilarity in conditions as much as possible. I do not admit that my suggestion that the cause of the disease may be due to deficiency of salt in the soil has been negated by the discovery of disease on trees growing even in the sea-shore, for the trees there may have been infected in the same way as healthy people with sanitary surroundings are infected.

In a former article I believe you stated that in your reply to Government you gave the probable consumption of Salt for coconut cultivation at 150 lbs. the acre, or 2 lbs. per tree. That is an excessively low figure. The value of salt in the cultivation of cereals is not established. The small quantity found in its ashes can, it is said, be supplied by the soil to which it is carried by natural means. In very rare instances is the benefit derived from application of salt to cereals apparent, and yet I lately stumbled on the opinion of Wrightson, professor of Agriculture at Cirencester, that salt ought to be applied at the rate of 5 cwt. the acre for wheat, and that it "has long been employed as a manure." The ash of the straw and grain of wheat contains but a very small proportion of salt, and yet 5 cwt. the acre is recommended to be used as a dressing for wheat; so that less than 1/4 of that quantity for coconuts, a product that has its home on a soil impregnated with salt, is absurdly low. I think that 1/2 a ton per acre for coconuts will be a very moderate dressing. Possibly your estimate was for the substance as a manurial agent, but I think the least value salt possesses is as a manure. It is useful 1st as a manure, 2nd as affecting the soil chemically, 3rd mechanically, and 4th for its hygroscopic properties. I have already discussed salt as a manure. As I said in a previous communication, it is said to render soluble the phosphates, nitrogen and potash in the soil as well as silica. Silica is the substance that stiffens all forms of vegetation, therefore salt may be of help to coconut trees to overcome the bad habit peculiar to trees in inland districts of requiring a support for their bunches of fruit. Salt keeps a soil moist, and therefore free, by the property it has of attracting moisture from the atmosphere, and last, though not least, cattle feeding on a herbage growing on a soil impregnated with salt are likely to be in good health and condition. So that, quite apart from the leaf disease, salt is of very great value to coconut planters. I advocate its use not in homeopathic doses as a manure, but as a top-dressing to the soil. Its value can be ascertained only by experiment, and this reminds me you have not made public the reply you received from the Government to your request for salt to experiment with. Surely, the Government could not have refused to give you a small quantity of salt for experimental purposes for fear it would affect the revenue prejudicially!

I will now summarise all the information I have on the value of salt. "Salt keeps the land cool and moist. It neutralises drought. It glazes and stiffens straw. It keeps the ground in such condition that fruits and grains fill plumply, however long continued the drought. Fruit trees manured with salt bear more fruit than when manured with compost. Ammonia, potash and phosphoric acid are rendered soluble by the action of salt. A leading scientist calls it a soil digester. It retards the maturity of a plant, thus lengthening the period of growth, and ensures a better yield. Impure salt is to be preferred, as it contains other valuable plant food. 57 per cent of the saline matter of blood is composed of salt, and this is partly discharged through the skin and kidneys, therefore a

Then we get a repetition of hints already given about "Bulking in the Factory," and advice as to quality versus quantity of the same purport as Messrs. I. A. Rucker & Bencraft advanced a year ago.

continuous supply of it is necessary to preserve health in animals. Salt spread on the ground aids in the solution of mineral matter used in stiffening the stems of plants. Salt is efficacious in soils abounding in organic matter. It is not a direct food for cereals, but by stiffening the straw keeps it from "lodging." Wherever it is needed it often pays its cost many times. Salt is useful for application to the manure heap to supply it with chlorine. Salt has been in use for ages as a fertilizer, and its great value cannot be disputed, it operates on the soil with an influence not produced by any other stimulant, mineral or vegetable." I have summarised the foregoing from the different volumes of the *Tropical Agriculturist* at much trouble, and hope it will help to awaken an interest in this substance. I find that Mr. Hughes too has contributed to the literature on salt. He says that "there is no doubt that salt is a most useful and cheap source of manure." I am glad to find that he too is of the same opinion as myself, that if it be mixed with an odorous substance, Natives, with their peculiar prejudices, will refuse to handle it, "much less bring the same in contact with their food." He suggests admixture with fish manure, dried blood or Peruvian guano. The latter will be best as being most odoriferous. Government should not harp on the same string, and say that it is possible to purify salt so denaturalized; they ought to be practical and consider whether it is probable it will be done. Let the experiment be tried for one year, of selling at reduced rates, not the salt used for food, but the refuse salt destroyed at so high an expenditure of money, with proper restrictions of course. If the revenue be affected, it will be time enough to withdraw the concession.—Local "Examiner."

THE HAVANA TOBACCO TRADE.

The importance of the tobacco cultivation as a profitable industry of Cuba is a well-known fact, but the extent of the trade, and the great money value of the produce in that single country are not so generally known. "The Tobacco Industries of Cuba" has recently been the subject of a carefully drawn up report to the Foreign Office, of which the following is a summary of the most interesting points:—

Cuban Tobacco has, it is stated, no rival in the world, and it is curious to note that this supremacy is confined to the western portion of the island, the Tobacco grown to the east of Havana having a distinctly different character. The leaf there is good—better than most foreign kinds—but is wanting in aroma and delicacy of flavour, when compared with the former. That of the eastern districts goes under the general name of "Vuelta Arriba," in contradistinction to that from the west, which is called "Vuelta Abajo," and this, again, is divided into "Medio Vuelta Abajo" and "Partido," the latter name being applied to the Tobacco grown in the districts near and about Havana. It will thus be seen that as regards Tobacco, Nature has placed Cuba above competition. It is this which has made her Tobacco trade a certainty—a natural monopoly, which is only a universal abstention from smoking or extraordinary climatic changes can break up. This valuable natural privilege has been a mainstay for the Cubans in their commercial disaster, for large fortunes have been made already in this trade, and want of capital is the only drawback to the attainment of greater successes. Very large profits have in good years been realised, averaging from 10 to 35 per cent on invested capital. In spite of these encouraging facts, foreigners, with the exception of a few Germans, have not hitherto invested in this branch of Cuban trade, probably owing to an impression that the handling of tobacco in all its stages was a speciality which only the natives could successfully manipulate, and this, to a great extent, is the case. The Spaniards have almost exclusively established and managed the factories, while the Creoles have supplied the skilled labour. The successful factory owners are nearly all from Asturias, Galicia, and Catalonia, and it is an exception to find other provincials engaged in this trade. This year, however

it is stated, will see a revolution in this direction, for these manufactories with world-known brands have for the first time passed into English hands and are already working for English account.

The Partagas Company (Limited) has been formed in London with a share capital of £295,000, and has purchased the cigar and cigarette manufactories working under the brand of the "Flor de Tobacco," with 18,000 acres of Tobacco land in the best part of the Vuelta Abajo for £200,000. This factory, which has a well merited reputation for high class aromatic goods, turn out between 30,000 and 35,000 cigars, and 2,000,000 cigarettes daily. Of this new experiment, it is said:—"If our countrymen do not hastily and imprudently replace tried native labour and management by foreign and inexperienced hands, there is no apparent reason why this undertaking should not give a good return on capital."

A second company has also been formed in London with a large capital, and now that the attention of Englishmen has been called to this branch of culture, it is expected that similar companies will soon follow. Companies have also been formed in Melbourne, Australia, for the purpose of securing a steady and direct supply of the best brands of cigars to our Australian colonies. It will thus be seen that not only is the British public becoming materially interested in this industry, but that our kinsmen in Australia are also alive to the chance of sharing in the profits and pleasure of the choice Havana leaf, the demand for which, as smokers' tastes become developed, ever increases.

Besides the cigar and cigarette trade, a large and lucrative business is now done in leaf Tobacco, of which thousands of bales are shipped to the United States and to Germany, some to be rolled there so as to avoid import duties, but the greater part to be mixed with, and so render saleable, the native and inferior product.

To reach and maintain the level of an eager and constant demand, it is necessary to know both how to select the leaf in the field, and how to cure and manipulate it in the factory. All the rest is simple enough for an intelligent man, but for these operations experience and instinct, developed by long practice, are indispensable conditions of success, the want of them and insufficient capital have been the ruin of numerous factories. It is by these qualities that the plodding and industrious Asturians have shown their strength and made their fortunes from small beginnings. It is stated that "the sudden irruption of nearly one million sterling of British capital into the Tobacco field has caused some alarm both in and out of the island on the ground that we are about to obtain command of the whole Havana trade."—*Gardeners' Chronicle*.

AGRI-HORTICULTURAL SHOWS.

The success of District and Provincial Agri-Horticultural Shows from one point of view, should not blind us to their failure from another. There are few things that can earn success all round, and these Shows are not among the limited number. Their chief professed object is to improve Native Agriculture, by offering a prize for special excellence in garden and field produce, and affording the Native agriculturist an opportunity of seeing in the products of others the excellence he has himself not been able to attain. It is to be feared that, so far as this object is concerned, the measure of success attained has been very small, if indeed Shows have not been unmitigated failures. Not only have those whom it is specially necessary to instruct not availed themselves to any appreciable extent of the opportunity of entering the lists as competitors, but they have not been as numerous as they might have been even as spectators. Without going so far as to say that they may not have benefited indirectly, it is as well honestly to point out the very limited direct influence exercised by Shows over them, in order that change of system may be devised which would be more fruitful of results. The important end in view justifies some effort. Even the most enthusiastic admirer of the Natives or their most earnest apologist does not question the need of improve-

THE TROPICAL AGRICULTURIST MONTHLY.

Vol. IX.]

COLOMBO, SEPTEMBER 2ND, 1889.

[No. 3.]

PREPARATION OF AND TRADE IN ALOE-FIBRE IN MAURITIUS.

We are printing below a pamphlet published in Mauritius in 1882, and translated for us in that year. Its publication has been delayed, in consequence of the very discouraging results of trials

with the "Death" machinery to obtain fibre cheaply from the leaves of *Fourcroya gigantea*, the very species of aloe which has been so successful in Mauritius. There it seems to spread and grow spontaneously and to be cultivated and prepared on a large scale, the export of aloe fibre from the sugar island having attained extensive dimensions. The plant could be grown to any extent in Ceylon, and the whole question hinges on the use of machines which will do good work and cheaply. Such machines seem to be available in Mauritius. In 1882, it will be observed, M. de Chazal stated that 3 per cent of the weight of leaves in fibre or 1½ ton of fibre per acre would pay him. As tea cultivation seems likely to be overdone, some of our readers may wish to turn their attention to the cultivation of fibre-yielding plants and to the preparation of the fibres. We therefore publish the long delayed translation, and we hope soon to get

further information from Mauritius, especially as to the machinery and appliances (chemicals being deemed objectionable) used in extracting the fibre from the leaves. The mode in which Manila hemp (*Musa textilis*) is dealt with in the Philippines is thus described by Mr. Wilkinson, British Consul at Manila:—

"Two strong uprights are firmly fixed in the ground and connected by a cross bar, in the centre of which a large broad-bladed knife is fixed downwards on a block of wood fastened lengthwise on the bar; the knife has a strong handle, which is connected by a cord to a long bamboo made to act as a spring by being tied in the middle and the butt parallel and above the bar; the free end thus forms a supple and powerful spring and holds the edge of the knife firmly against the block; below the bar there is a treadle attached

by a cord to the handle of the knife; the mode of operation is for the worker to stand opposite the knife placing either foot on the treadle, which he depresses, thus forcing the knife handle down and the blade up; he then places a strip of stalk (called locally *sifa*) between the blade and the block leaving only enough to wrap round a stock on the near side; he then releases the treadle and the knife by the action of the bamboo spring nips the strip firmly against the block, and on the workman drawing the strip through the pulp is left behind. The apparatus is extremely simple and inexpensive."

"In the *Bulletin* for April 1887 (No. 4) published by the authorities of Kew, there is a great deal of interesting information regarding the Manila hemp. It is there stated that the whole supply comes from the Philippine Islands; the imports to Great Britain "amounts to about 170,000 bales and to the United States about 160,000 bales, equal to about 50,000 tons per annum." The imports to Calcutta are comparatively insignificant, being probably less than 300 tons per annum. It is stated in the Kew report that a labourer working under pressure "can clean nearly 20 lb. of hemp per diem; but as a rule the quantity cleaned by one man working steadily day by day averages about 12 lb.; usually two men work together, one cutting down the stems and splitting them, while the other cleans the fibre. At the current rate of wages in 1879 one labourer's earnings were 7½d. to 8d. per diem."

ALOE FIBRE AND ITS PREPARATION.*

BY EVENOR DE CHAZAL.

(Translated by "Károly Fűröd.")

PREFACE TO THE SECOND EDITION.

The cordial welcome which this little book has met with at the hands of the public since its first edition, which was brought out at the expense and by the order of the Chamber of Agriculture, the sustained demand of which it has been the object in various directions,—a demand which has led to its exhaustion,—above all, the growing favour which the new industry enjoys, have encouraged me to bring out a second edition.

The only pretention to which this essay has aspired has been to call public attention to a new product, till then little known, but destined, in the opinion of a small number of followers, to march side by side, in the near future, with the great suga

* De la Fibre d'Aloès, et des Récents Perfectionnements apportés dans les Procédés d'Extraction. Etude lue à la Réunion de la Chambre d'Agriculture du 19 Janvier 1882. Deuxième édition. Maurice: *The Merchants and Planters Gazette*. 1882.

industry in this colony. Its appearance has coincided with the discovery of new appliances, which have given a considerable impulse to the manufacture, because they lower the net cost of the fibres, and also with a rise of the article in the London market. These two causes united have brought about quite a revolution among us. Important affairs have been seen to take place in a few months; new companies have been formed; large extents of ground have been bought at prices which the former proprietors of land long depreciated no longer hoped to secure; works have been erected; and motion and life have all at once flowed into those vast solitudes of the coast, deserted since the disappearance of the cane.

It has been thought fit to accord to this pamphlet the honour of this transformation.

I will not have the false modesty to think that it has not helped towards it; but I believe that my duty is to make known the true causes of the industrial revolution which has just taken place, and to name the authors of it:—it is those who were not afraid, at the first news of the progress realized, to invest their funds in the new companies,—who, as partisans convinced of the great future reserved for the hardy plant, have not hesitated to devote themselves entirely to it,—and who, sympathizing spectators of the struggles of the early days, have understood that the moment had come for them to lend their effective co-operation to a work which was to endow the country with an important source of wealth, and have contributed in a large measure in overcoming the last obstacles.

One is, indeed, astonished on ascertaining what immense progress this extraction of aloe fibre, so long despised, has realized in so short a time. To be convinced one has only to cast his eyes over the list of societies formed in these last six months, all of which also are in a flourishing condition, though of recent formation.

The following are the principal in the order of their appearance:—

1. *Rouge Terre Hemp Estate Society Limited*, established with a capital of R140,000, and producing about 1,500 lb. per day;
2. *Palmyre Hemp and Sugar Estate Society Limited*, established with a capital of R180,000, and also producing 1,500 lb. of fibre per day, but lime and sugar besides;
3. *Massilia Hemp Society Limited*, established with a capital of R120,000, and producing 20 tons of fibre per month;
4. *Mou Choisy Hemp Company Limited*, established with a capital of R400,000, and producing 30 tons per month;
5. *Vale and Black River Hemp Company Limited*, established with a capital of R450,000, and producing 40 tons of fibre per month;
6. *The Mauritius Hemp Company Limited*, started with a capital of R180,000, and producing 1,500 lb. per day;
7. *La Soci  t   de Yemen*, R300,000, and producing fibre and vanilla;
8. *The Albion and Gros Cailloux Sugar and Hemp Company Limited*, established with a capital of R1,500,000.

Beside these joint stock Societies, a great number of private concerns have been set up, of which the principal are:—

1. *Vertou*, by M. de Mars, producing from 12 to 15 tons per month;
2. *Palma*, by M. Bonieux;
3. P. Toulet at La Montagne Longue;
4. D'Unienville, at Beau Bassin, one of the promoters of the industry, and long at work;
5. Vally, at La Petite Riviere, producing a superior quality; and extremely particular as to the article that he delivers;

6. J. Cauvin, at Les Pailles;

7. M. Vigoureux, at Les Bambous, who not only cultivates vast extents of land covered with magnificent aloes, but is also planting up on a very large scale;

8. *Balakhava*, by Messrs. Samuel Baker & Co., whose machines are put into motion by means of a powerful hydraulic apparatus;

9. Lastly, *St. Antoine*, which combines the latest improvements and will soon begin producing.

All are active; many produce over one ton per day—and some are already yielding dividends. This is not all. Everywhere planting is going on, and after a lapse of less than five years all that shore where nothing grew beside the "old maid" will be found valuable and entirely covered with aloes.

But it is not in Mauritius alone that the industrial and commercial world has been moved: our neighbours of the sister-isle, prompt to follow us in our advance, have adopted our processes, and have set themselves seriously to work. Less enterprising, less assisted, but as courageous and active as those creoles of Mauritius who were lately dubbed 'Lotus Eaters,' and whom people in certain circles persist in considering as attacked by *lethargy*, they have in their turn, with the help of some of our compatriots, acclimatized in their country our apparatuses, and are to enter upon a severe but happy competition with us.

If we look further afield, we see that in Ceylon they are giving us attention—as witness this letter which I have received by the mail from the editor of the *Ceylon Observer* at Colombo:—"We should deem it a great favour if you would send us a copy of your work on Aloe Manipulation.—Signed: A. M. & J. Ferguson." It is the same in Australia, the Cape, Natal, America. From all quarters our experiments are followed with interest, and our mode of procedure is sought to be adopted. Aloe fibre has henceforth its distinct place in commercial transactions, and it is to the island of Mauritius that modern civilization will be indebted for this important article, which will always make its way, forcing itself more and more, at first to the brush manufactory, to the makers of ropes, to the navy, and afterwards to the manufacturers of the finest and choicest textures. We have the right then of being proud of the result obtained, and that of hoping in the immense future which is opened out to us.

Every medal, however, has its obverse: and ours lies in the enthusiasm with which the birth of the new industry was received. We must be on our guard against the danger which may result from a hasty and badly-finished manufacture. If it is true that we have ended by winning the first place, it is no less true that we have only reached it by the force of patience and pains. Nowadays, in order to bleach the fibre, some have lost sight of this fundamental warning, incessantly formulated by our buyers in the English market: "No chemical process." They also add, it is true: "The longest, the whitest, and the softest possible," and it is to obtain one of these desiderata that sulphurous acid has sometimes been employed, or chlorine and its derivatives, such as the hypochloride or the chloride of calcium, in order to bleach the fibre. These means are bad, and they cannot but lead to a fall in the price of our manufacture. And the day that we sow distrust in the market we shall have great difficulty in restoring the paying prices that we are now actually realizing.

We must guard then against employing any chemical means which may be of such a nature as to diminish the strength of resistance of our fibres; the greatest attention must also be paid to the packing, and it must be seen to that the fibres are not put into bales till they are perfectly dry, for the least damp causes mould, and consequently the depreciation of the article. We must, in fact,

endeavour always to produce a manufacture of the first quality which shall reserve to us a rank which is soon to be hotly disputed, and not forget that the recommendations of the commercial houses which serve us as intermediaries are invariably to make the longest, the whitest, and the softest possible, and to avoid the use of chemical processes.

I have nothing to add to what I have said in this pamphlet on the recent improvements wrought in the apparatuses for extraction. It has not come to my knowledge that these have been sensibly modified in their construction since the day when I drew attention to them. The progress which may have been realized in this regard depends above all on the careful cultivation and the pains taken with the manufacture. Such as they are these machines are sufficient, and they can await the improvements which will not fail to suggest themselves, especially nowadays when so many interests are engaged in agriculture.

I must, however, mention the experiments that have been made in this direction. Several new machines are in the course of construction, and I myself have an interest in two. However, I do not believe the time has yet come to speak of them in detail. It is enough that it be known that we are not asleep, and that we are aware that the *statu quo* in the matter of commerce is equivalent to an abdication. The law of progress finds its application here as elsewhere. From America there has lately come to us a new machine, which is under trial at this moment. It is as usual a wheel armed with paddles which scrape upon a surface sometimes movable, sometimes fixed, and one which does not differ from any others except in very unimportant points.

Finally, I wish it to be clearly understood, that, of what has been done in the way of inventions, our merchants possess that which is the most simple, the least costly, and which calls for the least exertion, while accomplishing the greatest amount of work. It only remains for me to wish them the confidence which commands success, and the perseverance which insures it.

EVENOR DE CHAZAL.

St. Antoine, 30th June 1882.

Mr. President and gentlemen, members of the Chamber of Agriculture,

The attention of the Chamber has been lately, and on several occasions, directed towards a new industry in the development of which I have taken a share large enough to believe myself justified in making it the object of a communication, especially at a time when an important improvement has just been introduced into it: I refer to the extraction of the fibre of aloes.

The proceedings of this Chamber have frequently made mention of the experiments which have been tried in this direction by some of our compatriots, and have many times included letters from the present Director of our Gardens, of whose devotion to our interests you are aware. In fact, during the voyage which he has just made round the world in order to supply our impoverished sugar industry with new species of canes, Mr. Horne has several times given us information regarding the aloe, its future as a commercial plant, and the possibility of extracting the fibre from it economically, by adopting known processes, especially those employed in New Zealand in the manipulation of the *Phormium tenax*; it was he also, who quite recently put us into communication with Mr. Wilson, a London engineer, to whom you have sent as a delegate our compatriot, Mr. George Mayer. You have been informed of the result of his proceedings.

Mr. George Mayer is not a member of this Chamber, but he is interested in the future of aloes, and he is well enough up in the question which engages us to have been able to appreciate the progress realized by the machines which Mr. Wilson is constructing for Mexico, and which have been offered to us. It is apparent from the report sent by Mr. Mayer to the Chamber that these machines are not in any point superior to those that we already possess.

But, gentlemen, while we were seeking on all sides for that perfection so much desired, it has just modestly come to light here, in the very midst of us, realizing all our aspirations, and finally established in a durable and definite fashion the industry which for several years has been dragging itself painfully along.

It is needful that I should tell you in detail how this revolution has been accomplished, because you will see in it, as I have done, the source of an increase to the public wealth. I do not pretend to present before you a complete work: my ambition is limited to collecting the scattered materials, to put in order the facts which have come to my knowledge, to fix undefined lines, to bring to your notice, above all, those amongst us who have been the first to enter a track, henceforth widely open to all, which has endowed our country with a new element of prosperity.

I. At the head of these men of energy, whom numerous failures at the outset have not disheartened, and whose perseverance has contributed to the foundation of the industry, my friend, George Bourguignon, naturally presents himself, the oldest surely of all those who have engaged in aloes in Mauritius. Although he has not been directly mixed up in the recent experiments which have resulted in the improvement I have pointed out to you, it can be said that but for him, but for his rare pertinacity, which has ended by triumphing over all obstacles, our country would still be in the gropings of the early days. Bourguignon, however, is not the only one who has occupied himself with aloes: there are others, not less energetic, not less patient than he, although of not such long standing, who have like him incontestable rights to the gratitude of posterity. I will cite, simply as they come to my pen, the Vallys, the Ryders, the Lecontes, the Troughets, the d'Unienvilles. And Cazotet finally, Cazotet, the Lavignac of aloes, the pertinacious seeker whom nothing has discouraged, not even the loss of a little fortune entirely consecrated to the service of his adopted country, a fortune which is on the road to building up anew on those same aloes which have twice ruined him. It is to the painful toil of these courageous men that we are today indebted for seeing our colony endowed with an industry, the rival of sugar, and destined to restore the value of our coast lands, the extent of which amounts to many hundreds of thousands of acres. These seekers had faith in their final success. Behold them rewarded at last. You will not begrudge them the tribute of praise which is their legitimate due.

II. Gentlemen, I would lengthen this essay considerably if I undertook to give you the history of all the machines that have been invented to succeed in extracting the fibre contained in this wild plant. I cannot, however, refrain from mentioning to you that the first thoughts were turned to the mills in use for crushing the canes. Here is what the illustrious Cossigny says on the subject in his remarkable work entitled "*Des moyens d'améliorations proposés aux habitants des Colonies*," Paris, year XI. This book, which displays an erudition as varied as it is extensive, has now become very scarce.

"The pita aloes afford the negroes, who derive great benefit from them, the material of all the ropes useful for colonial dwellings, where they supply the place of ropes of hemp and flax. This fibre serves to make all that is necessary for harnessing animals of draught and of burden.....The threads of the pita aloe are employed in Manila to make pretty thick stuffs, which are tinted blue, and with which the natives clothe themselves. Once I bought two hundred pieces at the Isle of France, which I distributed to the negroes on my settlement: they made petticoats of them. These stuffs have served me also in making sieves. I am not aware if, at St. Domingo and even at Manila, they soak the leaves of the aloes to separate the threads. This operation does not appear necessary when they are employed to make cordage; but when it is wished to manufacture cloths, the soaking would render the threads more supple and more durable. It is probably to the want of this operation that the fibre owes the stiffness which it always possesses. Then the juice of the leaves could be expressed by causing them to pass between the cylinders of a sugar-mill; then they might be put to soak for some days in stagnant water, which, aided by fermentation, would dissolve the gum which they contain; after which they would be washed in the river. I do not know whether the juice expressed from the leaves, put over the fire to evaporate, would not yield a gum fitted for some purpose. This could be easily proved. I commend these trials to the patriotism of the Colonists.

"In the Isles of France and Bourbon we pay no attention to our pita aloes, which spring up very freely in all sorts of soils, without any care whatever: scarcely is any use made of the leaves of the pine-apples, which possess great durability and which are preferred by the Chinese, especially for fishing. Beside the pita aloe, which we ought to multiply for its fibres, we ought also to cultivate the aloe of Socotra, in order to obtain the gum-resinous extract which it furnishes, and of which there is a great consumption in India and Europe. The Dutch colonists possess this industry at the Cape of Good Hope. It seems to me that they could also extract fibre from it. This plant would then yield two most useful products."—(Vol. I., Obs. XXIV.: p. 155 and following.)

And further on:—"Beside the hemp and the flax, we have in our Eastern colonies many plants which furnish fibre. I will first of all mention the two species of aloes which they have in the Isles of France and Bourbon, and which grow in the driest and most arid places. It seems to me that these plants are those which promise the greatest advantages," &c.—(Chap. XVIII, Vol. II., p. 407.)

Starting with this principle that it is necessary to bruise the leaves to cause them to rot easily, use was, as I have told you above, made at first of the cane-mills, but it was not long before it was seen that the cylinders cut the filaments, and the system was abandoned. It was the same with the soaking because of the lack of water. Later on mechanical beaters were made use of, imitating the human hand. The courtyard of my friend Bourguignon is still encumbered with these crude experiments, which witness to the variety, and at the same time to the sterility, of the first experiences. At last came the *scraper*, whose paternity has been claimed by many inventors, and which it is impossible to attribute to anyone. This is not Minerva sprung fully armed from the head of Jupiter: it was born from the laborious and common action of all the manufacturers of fibres, who have all and turn about more or less modified and perfected it. The principle of it came to us from America,

III. The present mode of extraction consists a

pulley, or, to speak more vulgarly, a wheel, about as large as an ordinary cart-wheel. This wheel is armed, over all its circumference, with spikes, or, if you prefer it, with scratchers, embedded in the wood and strongly fixed by means of bolts. There are of them about 14 or 15 on the whole circumference. If the wheel is 5 feet in diameter, and there are 15 scratchers thus disposed, it follows that they will be a foot apart from each other. This pulley, which is the soul of the machine, rests on trestles well bolted into their foundations: it is set agoing, like all machines of this sort, by some motive power and by means of a transmitting shaft like that for turbines. Imagine now, in the front of this pulley, which makes 400 or 500 revolutions a minute, imagine a table, like that which is found in front of the cane-mills, only narrower, and at this table a block of wood against which the scratchers of the pulley beat. This block of wood is the *servant-maid*. It is regulated by means of a screw placed behind, and plays a very important rôle in the progress of the machine, for according as it is too tight or too loose, the fibres are cut or are not sufficiently scraped. There must be between this *servante* and the scratchers a space extremely exact, seeing that all depends on how the servant is regulated. I will not occupy my time in speaking to you of the little fluted cylinders placed in front of the machine, for they are only an accessory, intelligent it is true, and even necessary: but they are not indispensable to my lecture and would only encumber it.

You have now before you what in the language of a maker of fibres we have agreed to call the "scratcher": put six or ten of them into the same building, and those amongst you who have not had occasion to see these machines at work will be able to get a general idea of them. Gentlemen, this scratcher is not perfect, but it is very near being so: and when it is seen at work it is remarked with astonishment what small force it exerts and how little it breaks the fibre. The workman who serves it stands in front: he pushes the leaves one by one, rapidly, *point first*. (Keep this detail well in mind.) The leaf, dragged by the rotation of the fluted cylinders, which are under the hand of the workman, and which, in the new machines of which I shall have to say something to you later on, they have altogether omitted, is scraped over its greatest length, and effects its return by the same road in the state of fibre with the exception of an end which varies from 6 inches to a foot in length, and which it is the custom to call the "heel." This is the thick end, that which is attached to the stem, and the stumbling-block in all the experiments made up till now. What ought to be done with this heel? Ought it to be cut off, as some have recommended, or ought it to be scraped? But this second operation cannot be done in the same machine. Well then, which is the course that ought to be adopted?

We will now, gentlemen, pass on to a new machine: the "head-splitter," the cause of all our misfortunes, which it is sought to suppress, and against which all our efforts have failed to the present day. It is essentially composed of a wheel identically similar to that of the scratcher, armed with scrapers like it, with the chief difference that instead of turning against a fixed *servante* it turns in a movable socket about 18 inches long, and forming a lever, or if you prefer it, a pedal. I have said that after having passed through the scratcher the aloe leaf, reduced to fibre throughout its greatest length, preserves a "heel." The workman charged with the second operation hangs up the scraped portion of the leaves in bundles of five or six at a time on a hook which juts out above the socket, half-open at his feet: then, placing his foot on the pedal, he imparts to it a movement from below upwards, while he causes

it to approach the wheel so that the scrapers, still revolving with the rapidity we have mentioned, take off what remains of the unscraped portion of the leaf, that is to say the "heel."

Well, gentlemen, this was the weak side of the industry till lately. It does not enter into my plans to reply in advance to all the objections that might be brought forward as to the defects of such a machine. It was simply ruinous as much by the force it exercised as by the violence with which it worked.

If the scratcher caused little waste the "head-splitter" on the other hand was defective in a grievous manner. Only, nothing else was found, and it was not known how to replace it. But why was the head-splitter so defective? It is not only because it exercised an excessive force which betrayed itself in an enormous consumption of fuel, seeing that it performed the work of a drag every time it was in motion, but also because it carried away a considerable portion of the fibres already scraped, which, not being attached to the hook on account of their shorter length, could not resist the tug and ran off with the refuse. Now, to understand why all the fibres could not have been fastened to the hook which overhangs the half-opened socket of the head-splitter, it is needful that we should know how the leaf of the aloe is formed not only to put ourselves in possession of the causes of waste, but to get the key to the progress that has been realized.

IV. The aloe, gentlemen, of which all the varieties which grow spontaneously in our soil are not uniformly profitable to our industry, the aloe is essentially composed of a stem around which group themselves spirally leaves varying in length from 3 to 7 feet to keep within the average. When these leaves examined carefully, it is seen that the part which adjoins the stem is the thickest, heaviest, and most fleshy part. The point terminates in a strong thorn. All the fibres necessarily start from the stem, but do not all end at the terminal point, as can be ascertained by tearing a leaf lengthwise. Those of the middle alone reach it; those of the sides stop midway. It follows that when an aloe leaf is cut at a certain distance from the stem, this distance varying from 6 inches to a foot, all the fibres have been cut at a similar point. If now we suppose that it is this end which will be scraped first, we shall be sure of seizing all the fibres at their starting point when the leaf has to be turned round to subject it to the second scraping. But, gentlemen, this was not how it was done. If you remember the leaf was presented to the machine by its terminal point first; then, when it was three-quarters scraped, it was turned round to present the heel to the head-splitter. In this second operation the longest fibres alone are retained on the hook; the rest are dragged away by the rapidity of the rotation of the wheel and are lost, so that the result of this second operation will have been, it is true, to scrape a heel of 6 inches or a foot in length, but will have been at the same time to destroy a part of the work done by the first machine, in snatching away some of the fibres already made by it because they were not long enough to be retained on the hook.

It is upon this important point that the improvement of which I have to speak to you has taken place. This does not consist solely but principally in the suppression of the "head-splitter," and its originality lies in its scraping the "heel" of the leaf before scraping the "point."

I have told you that the process did not consist solely in the fact of causing the heel to pass before the point. In truth, the *servante* plays a considerable part in the progress which has been realized; its regulation, the new shape that has been given to it, the new materials of which it is made, constitute so many perfections which have to be

added to the mode of presenting the leaf, and contribute to increase the returns.

I have thought, gentlemen, that the Chamber could not remain indifferent or strangers to all that has been accomplished in this line of thought, and that it is its duty to direct and sustain the movement which has begun. An industry is about to be founded on solid bases, it is real, it may bring to the colonial treasury a considerable increase; to develop itself it only asks for its support and a little publicity, that it may find in disposable capital that assistance to which it certainly has a right, because that right is now based upon an incontestable success.

V. It is generally admitted that aloe leaves give an average return of 2 per cent. Here we must explain ourselves; when we say 2 per cent we do not say 2 lb. of fibre for 100 lb. of leaf, but 2 lb. of fibre for 100 leaves, which is not quite the same thing. Whatever may be the defect in this calculation, it must be accepted as it is, for this is the way the manufacturers of fibres understand it, and because the leaves are more easily counted than weighed, and because, moreover, if the proportion of the weight of the fibre to the weight of the leaves were adopted, it would offer other inconveniences of which the least would proceed from the fleshy part, which yields a very different percentage according to the distance it is cut from the stem. I will not, therefore, insist any longer on this point but content myself with noting it, because it will serve as the basis of our comparisons.

However I may desire to avoid speaking to you of what is personal to myself, yet I cannot forbear mentioning to you that during my three years of manufacture at *Rouge Terre* my proportion has constantly been below this 2 per cent. In 1878 it was 1.76; in 1879 it was 1.62 per 133 leaves, and 1.85 in 1880, that is to say, I only succeeded in extracting from 100 leaves brought to my manufactory about 1½ lb. of dry fibre fit to be packed. You will see with me that this result was ruinous; consequently, I closed my factory and waited for better days. I have equally acquired the right, because I have asked him for it, of telling you the result obtained by my brother-in-law, Edward Trouchet, at *La Riviere Noire* during three years. He has been scarcely more fortunate than I, his average having been 1.97. I will not allow myself to speak to you of others, although I am led to think that the result reached by them has not been much more favourable. I will make an exception, however, of my friend George Bourguignon, who has reached, I am told, 2½ per cent. This result does honour to his management, and above all to his process of extraction. If you compare these figures, be they 2 or 2½ per cent, with those of the cane which rise to 9 and 10 per cent of its weight, you will ask yourselves how an industry can be maintained with such returns. To be frank, it is maintained with difficulty. For my part, I declare that if I had only obtained the 2½ per cent of my friend Bourguignon, I would not only have not closed my factory, but I would have made large enough profits to have never dreamt of doing so.

But, gentlemen, it is not a question today of 2, nor even of 2½ per cent. It is at least 50 per cent above that that must be counted upon, as I will try to prove directly. And you will admit with me, that if it was possible to live with 2 per cent and even less, one has a right to believe in success when this same leaf gives a minimum return of 3 per cent, often more, without an increase of expenditure, and on the contrary with a motive power infinitely less.

Here are some experiments made by me at *Palmyre* on the 13th September with the new apparatuses:—

(1) 50 leaves of average size, 4 feet long, weighing 56 lb., gave of dry fibre 1.75 lb., that is 3.50 lb. for 100 leaves, or 3.12 lb. for 100 lb.

(2) 5 leaves of Madagascar aloes 7 feet long weighing 24 lb. gave 0.49 lb., that is 9.80 lb. for 100 leaves, but only 2.03 lb. for 100 lb.

At *Mont Choisy* in the machines of M. Cazotet I passed 25 leaves weighing 42 lb. which gave 1.23 lb. of dry fibre, that is 5.12 per 100 leaves and 3.05 per 100 lb. The present average of M. Cazotet with the new machines is from $3\frac{1}{2}$ to $3\frac{3}{4}$ lb. per 100 leaves. At La Rivière Noire, with Trouchet, it is lower, but the deficit must be attributed to the small leaves and perhaps also to the lack of experience of the men, who have not yet acquired the knack of serving the new machines. Lastly, with M. Bonieux, at Tombeau, they have arrived at 4.16 lb. per 100 leaves for the average work of a week.

You see, these numbers are infinitely superior to anything we have obtained till now, since they represent an average of 3 to $3\frac{1}{2}$ lb. of dry fibre per 100 leaves, whilst with the old machines scarcely 2 per cent, or by the most favoured $2\frac{1}{2}$, was reached.

Who then, after all, you will say, is the happy inventor of the new process? I touch here, gentleman, upon a delicate subject, and would not say anything before you of which I was not absolutely certain, as these remarks may perhaps see the light of publicity. My impression, however, is that it is a collective work of which no one can claim the paternity. Several have put their hands to it and have modified it, often with advantage. Here, besides, is what I have been able to gather on this point; I give it with all reserve, and am ready to make honourable amends if I should inflict injury on any interests.

When the Government published the notice which you are aware of, and by which it offered a prize of R2,500 for the best machine for extracting fibre from aloes, the committee, of which I had the honour to form a part, found itself in the presence of three machines none of which combined the conditions of the prize. The first, the Marabal machine, did not complete the leaf; there remained a "heel," which necessitated the employment of a head-splitter. The second, invented by M. Vigé, was not finished, and has never, to my knowledge, worked in a satisfactory manner, although it possessed some grand qualities. The principle sought by M. Vigé may be some day revived with advantage.

Finally, the third by M. Digard, made at the premises of M. P. d'Unienville, and with his help, has never been worked either. It took the leaf by its point like its predecessors, and has been patented. M. Digard, having left for Natal, handed it over to Messieurs Bax and Perdreau who had, it seems, advanced the funds, and who delivered it to M. Cazotet. The latter has modified it, has preserved its barrel, and originated the idea of causing the leaf to pass heel first. However, this process is discovered in the Marabal machine, so that its paternity could not even be attributed to M. Cazotet, although the considerable part which is due to him in the application of the new process cannot be disputed. This idea has been taken up by Messieurs Mérandon and Bonieux, and still further modified by them in the form of the barrel, the number of scrapers, and above all in the *servante*, which, as you have seen, plays an important part in the scraping of the leaf.

VI. A writer of talent, gentlemen, known and appreciated, Dr. J. Forbes Royle, has devoted to the aloes a chapter of his remarkable work on the textile plants of India.*

I must renounce the pleasure of transcribing it in its entirety, however much interest it may otherwise present, and I limit myself to extracting the following passages from it:—

* J. Forbes Royle, M.D.: "The fibrous plants of India, fitted for cordage, clothing and paper," page 43. London: Smith, Elder & Co., 1855.

"The agave is originally an inhabitant of America, but it is so widely diffused over the surface of the globe, that it appears to be indigenous to Africa, India, and the south of Spain. The agave, to which the name of *American Aloe* is so often given, resembles the aloe by its sword-like leaf; it has parallel veins, and attains a length of 8 to 10 feet from the stem to the point: it terminates in a strong thorn. It is this which renders this plant so useful for hedges and enclosures, and so sought after for this purpose in Italy and Sicily. It is completely developed at the end of three years, but does not flower before eight and sometimes twenty years. At this period they throw up a candelabra-like stalk. It is doubtless this peculiarity which has given birth to the fable that has been invented that these plants only flower once in a hundred years. It is in the leaves of this plant that the fibre is found. It is exceedingly long and tough, and cordage of great value is made from it. The juice, which flows from it, is sometimes, according to Long, substituted for soap.

"The fibres of these agaves are sometimes converted into ropes in Mexico, and these ropes often serve in the mines and on board vessels. Humboldt has given a description of a bridge over the river Chambo at Quito, 131 feet long, of which the main ropes, 4 inches in diameter, were made of the fibres of aloes. It is reported that in the West Indies the negroes make ropes, fishing nets and hammocks with the aloe fibre. The fibre is prepared as follows:—First the longest leaves of the plant are cut off, and then they are scraped with a bar of iron, which is held in both hands, till all the juice and pulp are expressed and only the fibre remains. Stedman says that the fibre resembles silk, and that the ropes made with it are considered in England as good as any others whatsoever, but that, however, they rot more quickly in water.

"In Portugal this fibre is called 'filo de pita,' and is applied to several purposes. In Spain it is also called 'pita,' and as the plant abounds in that country, ropes of all dimensions on a large scale have been made from it.

"The fibre and the rope of 'pita' are in the south of Spain, the object of a pretty large trade, but we must not deduce from this that the sources of a manufacture exist there, for all of it is done by hand. M. Ramon de la Sagra recommends the introduction of new species from Guatemala and Columbia, where they are known under the name of 'Cabula' and 'Cocaiza.' There are species of 'fourcroya' which also give excellent fibres. The 'fourcroya gigantea' is common at St. Helena, and has been introduced into Madras. The island of Madeira sent fibres of 'pita' to the Exhibition of 1851; we have had some aloes from the Barbadoes and Demerara. Mexico has sent yarn and paper made from the *Agave Americana*.

"The name of 'pita' seems also to have been given to similar fibres obtained from the *Bromelia* and *Yucca*, as well as from the *Agave*, according to Dr. Hamilton of Plymouth, and it is probable that this has been the case because they greatly resemble each other. Dr. Hamilton says also that this fibre is a sixth less heavy than hemp; this fact has importance and significance for vessels; he considers it also more tough and durable than hemp, and prefers it for cables, fishing-nets, &c., because of the facility with which it stands moisture. In an experiment that was made by H. M. Ship 'Portland,' a log-line 300 feet long of 'pita' fibre only shrank 16 feet, whilst a hamper rope of the same length shrank 21 $\frac{1}{2}$ feet; moreover the contraction of the 'pita' ceased on the third day, whilst that of the hempen rope lasted all the time. The two ropes were deposited in the stores at Plymouth Dockyard."

“Labillardière relates that at Amboyna the natives obtain from a bastard aloe, commonly called ‘Agave Vivipara,’ a long and fine fibre, equal to that of our best hemp. The Agave grows well in the north of Africa, and the French, since their occupation of Algiers, have paid great attention to it.”

I regret being obliged, gentlemen, to shorten this quotation. Dr. Forbes Royle enters into many details on the resistance and the durability of the aloe compared with hemp; and in these experiments it is always the aloe rope that has the superiority. So at Paris, an aloe rope, coming from Algeria, supported a weight of 2,000 kilogrammes [4409·20 lb.], whilst Manila hemp of the same size was only able to sustain 400 [881·84 lb.]. At Toulon, the fibres having been plunged into sea-water for six months, the aloe sustained a weight of 3,810 lb., whilst the hemp could only support 2,538, leaving a difference of 1,272 lb. in favour of the former.

Finally, according to experiments made by Mr. Hornby, and sent by him to the Agricultural Society of India, the aloe ropes were constantly found superior, not only for toughness, but for endurance, to the ropes of any other source, such as ‘jute,’ ‘manilla,’ ‘abaca,’ &c. The chapter ends with these almost prophetic words:—

“The fibre is quite good enough to furnish an article of commerce of the first order, destined to have a considerable value in the future, especially since the prejudice against white ropes is inclined to disappear. It is to be wished that serious experiments were made to arrive at a knowledge as to what are the best conditions for cutting the leaf, and also as to whether the fibre cannot be extracted by mechanical means. When preparing the ropes care also must be taken not to cut the fibres while twisting them; this is a delicate operation and ought to be done by professional rope-makers.”

VII. Gentlemen, all those who have traversed the dry and rocky plains of the coast, and by the coast I mean all the lower region of the Island to a distance varying from three to four miles from the coast to the centre of the Island, all those, I say, who have had occasion to traverse these regions, and you all certainly have had occasion to do so, must have been painfully impressed by the aridity and sterility of a land, which was formerly the principal source, one may say the origin, of the public fortune in this colony. It was there, in fact, that the finest factories were erected, that the great fortunes were built up, that the aristocracy of the Island lived. How many years has it needed to render these localities, formerly so fertile and populous, deserted and desolate? A half-century barely, a half-century, when in another country the depth of the soil, the moisture of vast continents, the rotation of crops, would allow landed proprietors to transmit to their descendants, from generation to generation, a land always generous and capable of supporting those who knew how to till them by the sweat of their brow. Gentlemen, fifty years has sufficed in Mauritius for the soil to be ruined, and the father has transmitted to his sons only a cause of ruin. I will not seek to find out who is responsible for such a state of affairs, because that would be to go beyond my limits. I will content myself with establishing it in passing. Well, gentlemen, this land which refuses to produce canes, where it is said that the *old maid* itself grows with difficulty, is the country of a vigorous plant which accommodates itself admirably to the desolation that surrounds it. This plant is the aloe. Alone, it animates with its luxuriant vegetation a desolate landscape, and in gaiety obtrudes itself upon the universal death of a nature always burnt up by an implacable sun, which the heavy rains of summer revive for a few days only. I invent nothing, gentlemen, and if the picture I

have drawn of these regions be exaggerated, I pray those of the members of the Chamber who hear me to stop me.

The aloe then comes there where nothing grows, in a land abandoned by the cane, without cultivation, without expense, fearing neither droughts, nor thieves, nor floods, nor cyclones, nor diseases, nor indeed the evils of all sorts that are accustomed to burst upon the cane, and which have pressed so hard the last few years, that it has become a problem to know how the inhabitants may succeed in withdrawing the interest of the immense capital sunk in this enterprise. Nothing like this for the aloe.

It comes by itself; and you, proprietors, formerly so chafed, now envied, for these plains of the coast, you have at length reaped the prize of your patience, and you are again going to restore work and comfort to the despised localities, whilst preparing for your descendants the means of honorably gaining their livelihood, and of rebuilding a fortune exhausted by the hard struggles that had to be fought in attempting to retain in these regions the dying out cane!

Plant, plant therefore. Do not forget that the aloe is the only possible product in these regions, that this product is extremely remunerative, that the roads you have made, that the factory you have erected, that the houses you have built, for the purpose of an industry that has quitted you to take refuge in the high and damp regions of the island, will soon be serving you for another product; that this product is more adapted to your soil than the cane, that it offers less risks, and that it can give as good returns as the most favourable sugar properties. You are at last going to see these roads again furrowed by rattling carts, this chimney, long extinct, again vomiting forth volumes of smoke, these deserted houses re-peopled, and the echoes asleep for so many years awaking with the tumultuous expressions of the joy and work of a whole population. Plant, and, believe me, do not lose a minute. The number of those who still smile, when the future of aloes is mentioned, daily diminishes. Plant! now above all when you have before you the machine which must create such a revolution, you cannot hesitate to plant. For my part, if I have succeeded in convincing a single one of those among you who possess lands at present uncultivated in these regions, I will have the satisfaction of having accomplished my duty, and will not regret the efforts I have attempted.

VIII. You have now before you an account which I have tried to make as faithful as possible of the present state of the industry. The essence of all I have just said is that the aloe gives now in fibre an average of about 3 per cent of its own weight, whilst with the old appliances scarcely 2 per cent was obtainable. I believe I have demonstrated that the extraction of fibres is at present a lucrative affair.

There remains the question of sale.

On this point I will be brief. It will be sufficient for me to say that aloe fibre, packed in bales, has sold in the London market, during the whole period that I have manufactured it, at an average price of £30 to £32 the ton. Just now the accounts of returns of the Blyth establishment show sales at £38 and £40, or an advance of £8 to £10 per ton. These figures possess eloquence and denote great stability in the article. They may also be explained in the following manner by this extract from the preface of Forbes Royle's work, already quoted:—“It has often been said that the only way of knowing the value of a fibre or any other product is the price which it realizes in commerce. This is very true for well-known articles; but if a new product is sent into the market, it is clear that few

persons will buy it, because it demands new machines to work it. I have been told that many years are needed before a new product can attract the attention of buyers. I readily believe it. This is one of the laws of commerce. We can see this by comparing the prices of jute with the former prices. It is plain, that in proportion as these new products intrude themselves upon purchasers, the properties are gradually taken note of, and their real value properly quoted," &c.

As for the planting, it is such an elementary operation that it appears to me idle to speak of it, the aloe being a hardy enough plant to be put out at any season. Vigorous specimens ought to be chosen as much as possible. One can plant all the year round, but naturally the rainy season is preferable. I have found it answer well at *Rouge Terre* to put my young plants into the old cane rows at a distance apart of 5 feet, so that an acre can contain 1,600 to 2,000 plants. As a general rule an aloe plant does not die if the root be covered. The plantation can be formed of young plants of that year or of plants of 2 or 3 years. I learn from my friend G. Bourguignon that plantations from seed succeed better. The older the aloes when transplanted the sooner do they flower; on the contrary, the younger they are the longer do they delay. It is the business of the owner to determine whether it is preferable to wait two or three years more in order to get several crops without having to renew his plantation, or whether he will find it more advantageous to enter promptly into production. I will add that aloes planted from seed or from young seedlings take 5 years to attain their complete development, whilst, if they are taken large, that is to say from 18 to 20 inches high, they take only 3 years. On an average aloes flower at the end of 7 to 8 years. They can then be cut 4 or 5 times before they have flowered and it becomes necessary to replace them.

With the new appliances the return may be estimated at 1½ ton of fibre per acre. At *Rouge Terre* my average has been from 1,700 to 1,800 lb. It has often happened that I have exceeded the ton with the bad outturn of the machines I used.

Gentlemen, I have finished. My friend, Albert Daruty, has been good enough to furnish me with some notes on the botanical part of my work. My brother, Régis de Chazal, engineer of the Forges and Foundries, has, on his part, consented to do the technical portion. This is the reason why I did not enter into a more complete description of the new machine of which I have spoken to you. On the other hand these descriptions may seem to resemble each other, especially in what concerns the 'scratcher'; on such a subject one cannot be too exact. My brother speaks as a specialist, I as a cultivator. I have scarcely spoken to you on anything that was not personal to myself; he describes to you the principal known machines; you will appreciate his essay.

I will say, in conclusion, to my colleagues, to my friends, to the proprietors of the coast lands: Plant. Four years are necessary for cultivation. In four years you will have the rudiments of a prosperity well earned. Establish your plantations around your factories so as to take advantage of your network of roads, and do not, in order to try and get returns sooner, go and set up your machinery in the midst of a field of naturally grown aloes. The industry is fixed and stable. It is a great mistake to believe that it will be an advantage to render it nomadic. Plant then, and be proud of the progress realized by our compatriots on this Mauritius soil, so liberal to him who knows how to work it wisely.

EVENOR DE CHAZAL.

St. Antoine, January 1882.

NOTES.

Here are the notes which I mentioned above, and which I owe to the kindness of my friend, Albert Daruty:—

The following species are found in Mauritius in a wild state:—

- (1) *Agave Americana* L. (Blue Aloe).
- (2) *Agave Angustifolia* Hano (Aloe with small leaves).
- (3) *Fourcroya Gigantea* Vent. (Green Aloe).
- (4) *Fourcroya Gigantea* Var. *Villemetiana* Roem (Cabbage or Malagasy Aloe).

Fourcroya Gigantea *Ventenat*.

The genus *Fourcroya*, of the family of Amaryllidaceae, separated from the genus *Agave*, was founded by *Ventenat*, and dedicated by him to the celebrated French chemist *Fourcroy*.

This genus was adopted by *de Jussieu* and other botanists, and *Endlicher*, in adopting it, gave it its true orthography *Fourcroya*, others formerly having written *Fourcroea*, *Fourcrocea*, and *Furcroea*.

Ventenat in dividing the genus *Agave* gave to the *agave foetida* the name of *Fourcroya Gigantea*: this is the species which now occupies us.

This plant was introduced into Europe in 1690, and it was only brought from Brazil to Mauritius towards the end of the last century by *Father Seriers*, almoner.

Aublet, who gives us this information, says that he cultivated it in the garden of the *Redouté*; it sent forth, he says, a huge branching stalk which, instead of flowering, was loaded with a great quantity of bulbs.*

The type of the species known in Mauritius under the name of *green aloe* is then a native of South America and the Antilles. It is a plant with a stalk sometimes very short, sometimes very tall; the leaves are erect, numerous, rigid, dense, slightly grooved, and disposed in rosaceous form at the summit of the stalk; they are glossy, of a bright green, about 2½ meters long [8·20 feet] by 15 to 18 centimetres broad [6 to 7 inches] exhaling a bad odour when crushed (whence the name *Agave Foetida*). The stalk is very tall, paniculated, rising to a height of 10 to 11 metres [33 to 36 feet] with a diameter of 15 to 20 centimetres [6 to 8 inches] at the base. Flowers pendant, white, having a bad odour, with filaments longer than the folioles of the perianth. Perianth persistent with six folioles multinerved, exposed, whose 3 interior ones or petals (are) larger and more delicate,—stamens 6, inserted in the depth of the flower,—anthers linear, oblong, sloping to the summit and two-lobed at the base, fixed by the middle of the back; varies with three multiovuled locules; style erect, thick at the base, fistulose, longer than the stamens; stigma obtuse with 3 angles or 3 boles; capsule? (not yet observed).

The plant here multiplies itself solely by buds, which are developed on the stalk, often in such a great quantity, that it is bent down by the weight.

The variety *Villemetiana*, which seems to have developed itself in Mauritius, does not differ from the type but by its leaves which are larger, greener, and less thorny, often even unarmed. This variety must have originated in the high, moist, and fertile spots.

A. DARUTY.

And now for the description of the machines, by my brother, Régis de Chazal, engineer at the Office of the Forges and Foundries.

The juice of the aloe is strongly acid on a litmus paper; it attacks iron and dissolves it very rapidly. It does not contain tannin, or at least in a very in-

* *Fusée Aublet*, *Histoire des Plantes de la Guyane Française*, Paris, 1775, vol. I, p. 305.

appreciable quantity, for the solution of iron is not black: cast-iron is scarcely affected, bronze and brass are not at all.

The leaf is composed of a bundle of fibres of different lengths, all starting from a common trunk or heel, and terminating, the longer at the point, the shorter at about the middle of the leaf. These fibres are surrounded, being united one to another, by a porous, white, and very juicy pulp. The younger it is the more juicy it is; at full maturity, that is to say when the leaf is yellow, it is nearly dry. The epidermic cuticle is a thin layer (about $\frac{1}{2}$ mm. [$\frac{1}{16}$ inch]) of a tissue much more compact than the pulp, less moist, and containing an appreciable portion of resinous gum; the dermis is dark green, the epidermis is only a thin transparent skin which comes off easily. The leaf dried becomes ligneous, the fibre has lost its toughness, the dermis adheres firmly to the fibres, and this renders it very difficult to separate the fibre from its envelope. It is then preferable to treat the leaf while green, as it is done now.

The maceration can be performed quickly enough, even in cold water, but the fibre undergoes a change: at first it becomes red, then black; it is, ordinarily, five times as strong as hemp, but must lose its toughness, for our consignees in Europe reproach us with sending them red fibres that are not prized by buyers: they attribute this deterioration to a defective packing, but I rather think, as has been remarked to me, that the fibre has not been dried enough. It must then redden in transit, thanks to its own moisture. In this case would it not be preferable to dry it at a stove before despatching it? Experience alone will show this. Under these conditions maceration is not possible. What renders this operation still more difficult is that the localities where the aloe is planted are arid and generally lack water, the irrigable lands being reserved for the cane, which is a product of higher cultivation.

It is said that an apothecary of Réunion has succeeded in preventing the change of fibres during maceration by means of a chemical product added to the water; I mention this detail with all reserve, not knowing the process. Fuel being at a comparatively high price in Mauritius, we are shut up exclusively to mechanical processes, acting on the leaf in a moist state, that is freshly cut.

What is the richness in fibres of the aloe leaf? This ought to be the first question to put, and the first to settle; however, absolutely nothing certain is known upon this point. Many experiments for this purpose have been made, but they do not appear to be satisfactory. There have been so many important discrepancies that no conclusion could be drawn from them. From 100 fine leaves, green and young, 8 feet in length, E. obtained 9 lb. of dry fibre calculated according to the ordinary proportion of green to wet fibre, which is about 30 per cent, which gives about 12.12 per cent of the weight. With ripe leaves, four feet long, he got 3.52 per cent. These fibres were obtained from the present machines; but he has not taken into account the waste, which would be but trifling. All this is far from being mathematical. P. and C. carefully scraped the leaf by hand and obtained 5.50 per cent (of the weight of the leaf). Some say it does not contain 3.50 altogether; others assert that it has a yield of 7 to 8 per cent. All this is very vague. It would be very important, however, if serious and continued experiments were made. Even commercially, it is impossible to get any precise record of the outturn of the different machines actually at work. P. maintains 3 English pounds of dried fibre for 100 leaves; M. affirms 3.40; B. 3.50 to 3.75; F. 2.16 to 2.48.

One of my friends who buys his leaves has no permanent expenditure on cultivation; he pays his men by the day, and keeps account of the profit which he makes in the following manner:—Two sets of 12 men each relieve each other in the day; the first represent his expenses, the second realizes the profit. He produces six bales of 150 kilos [330.69 lb.] a day. Another one manipulates 3 bales of 175 kilos [385.80 lb.] per day. He has 6 scrapers of the new system, a motive power of 8 horses, and a generator of 30, plus the transmission of motion. The newest, set up and working, would cost from 5,000 to 6,000 piastres in Mauritius.

Here now is a sketch of the different machines employed in the extraction of aloe fibre:—

The blacks content themselves with striking gentle blows on the leaf with a piece of wood, in such a manner as to bruise the pulp and render it less adherent to the fibre; then they scrape the surface (always by hand), and little by little remove this pulp. This is the principle of one of the first machines at the outset of the industry; it was composed of a certain number of blades set in a circular piece of wood movable upon an axis, and moved alternately by a shaft with cams; these blades strike very rapidly upon a surface on which the leaves are arranged. The result was to disintegrate the pulp, and to render it more easy of removal. The same end was attained in a primitive fashion by drawing over the leaves a heavy stone roller such as is used for smoothing grass. These two systems have been abandoned. Later on a pulley was employed of about 1.50 metre [5 feet] in diameter by 25 centimetres [10 inches] broad; on the felly following the generator were placed combs of copper of the width of the pulley; these combs had teeth 6 to 8 millimetres [$\frac{1}{4}$ to $\frac{1}{2}$ inch] in length; there were 6 to 8 combs on the pulley, to which a rapid rotatory motion was given. The leaf was firmly forced against these combs, and it became scraped. This was abominable: the teeth of the comb penetrated the leaf and broke the fibres.

Here are the modifications that were made at first of this machine, which, defective as it was, served later on as a type for the new ones which have since been constructed. The principal drum, which is a wooden wheel of 5 feet in diameter and 9 inches broad at the felly, rests on an axle placed horizontally on bushes. On the felly T irons were fixed at first of copper, and then of iron. There were 10 or 12 of them. The edges of these grooves are without teeth and slightly rounded. To the pulley is given a rapid rotatory motion by means of a pulley and strap. A little lower than the centre is found a joist *S* of hard wood (fig. 1) 4 inches in thickness and of the same width as the pulley. This piece is solidly fixed to a frame. Above and near the pulley are situated two small fluted cylinders *a* and *b*, of copper, gearing together, and having a length equal to the breadth of the pulley; the bushes of the axle of the small cylinder *b* are fixed, those of *a* are fastened to springs which allow the cylinders to recede and advance. *a* is moved by attraction; *b* receives its motion by a play of conical gearings and an apparatus which allows of giving at will equal and contrary rotations. The joist *S* or catch is regulated according to its separation from the pulley; it is cut roughly as the sketch indicates. The pulley turning in the direction of the arrow *F*, the leaf is introduced by the point between *a* and *b*; it is dragged rapidly in the direction of the arrow *f*; at the moment when it is about to pass through entirely the apparatus is acted upon, and *b* is caused to turn in the opposite direction and leads the leaf back. It is in this retrograde movements that the leaf, pressed against the catch and struck by the T irons,

is scraped; there comes out a skein of fibres adhering still to the "heel," which has not been scraped. This heel is a thick and fleshy portion.

In order to scrape it, the following machine, called by the makers *rattletrap*, is employed, (fig. 2). It is the very same pulley turning in the same direction. Only instead of the preceding catch, there is a *savate* *S*; this is a plank having the form *AS*, movable round an axle *A*. A roller *r* rests against the exterior surface; this roller is supported at the extremity of a lever *l* movable round the axle *a* which is fixed; at the other extremity a rod *b* fastened to a pedal *p* movable round the axle *d* which is fixed. On pressing with the foot upon *p*, *S* is pressed against the pulley, and on withdrawing the foot *S* is allowed to fall back, and it goes away from the pulley. At *c* is a hook fixed to a piece of the framework of the machine. And now for the working: the skein of fibres which comes out of the preceding machine is taken and fixed to the hook by rolling it round several times and letting the unscraped heel be taken; at this moment the *savate* is down, the pedal is pressed upon and this raises the *savate* *S*. This in its progress drags the heel and presses it firmly against the pulley, and the scraping begins; the reserve motion is put into action and the bundle of fibres is taken out completely scraped. These fibres, still moist and gummy, are put for 12 to 15 hours in hot water, then dried and packed. This proceeding is rough and coarse; the loss also is very great in this *rattletrap*; these are the machines which were used at Rouge Terre, and which are still used in two or three places.

The second machine which is about to be described is an improvement of the first in its mechanism. This is the machine invented by M. Marabal and constructed by Messrs. Rosnay & François, which has worked at Rouge Terre pretty regularly for nearly a year. I will not enter into any detail of construction, for it is rather complicated. This is the principle of it: *T* is a drum (fig. 3) of cast-iron backed by a good thickness of hard wood. At *m* is a chop, set into the wood; *t* a table doubled at *p* by a leaf of thin copper; *P* is a copper comb; *T'* a scraper in cast-iron with grooves absolutely similar to those already described; only it has a less diameter; it is about two feet. The movement of the drums is in the direction of the arrows *f*; the drum *T* turns with a speed of 30 revolutions per minute, *T'* of 200 or 300 revolutions. The following is the working:—The leaf is presented on *t* by the heel; the automatic comb *P* buries itself in the heel, and pushes it on at the moment when the chop *m* presents itself on a level with the table; the chop, which is automatic, is open; it closes rapidly and grips the heel, dragging with it the leaf, and forcing it against the drum; the rotation continuing, the leaf arrives at *a* where it is cleaned by the scraper which turns in a reverse direction. The scraping continues till the chop arrives at the position *m* indicated in the sketch. This latter then opens, and rejects the leaf by a rapid movement on to a leaf of sheet-iron *P'*, where it is gathered up. Then the chop takes up another leaf, and so it goes on.

Here, again, it is the point which is scraped, and there remains a heel. There is indeed a *Marabal*, *rattletrap* but it has been put aside, and it never acted satisfactorily. At Rouge Terre they made use of the *rattletrap*, described above, in order to crush the heel.

It must be remarked here that in these two machines the leaf has a reverse movement from that of the scraping drum; this is a main point which has caused the Viger machine, which is now about to be described, to be rejected.

It is essentially composed (fig. 4) of a large drum *T*, of polished cast-iron, 2½ feet in diameter, turning round an axis *A*; three small cylinders *c*, *c'*, *c''*, of cast-iron, mounted on axes turning in bushes; scrapers *G* and *G'* in cast-iron, with *T* irons are supported by a triangular balance *a b d* movable round an axis *a*. To this balance is fixed a rod (which is not represented in the sketch); at the end of the rod a small wheel which revolves on a wedge-shaped cam upon the axis *A*; the balance thus receives an automatic and periodical oscillating motion. Lastly at *S* is a metal plate acting as a guide to the leaf, *c*, *c'* and *A* are furnished with a tightening screw for regulating; *c* touches *c'* but does not touch *T*; *c'* touches *T*; and so does *c''*. The directions of the rotations are indicated by the dotted arrows, the passage of the leaf by black ones. The drum, the cylinders, and the scrapers have an equal length of 6 feet, and are contained between two vertical frames of cast-iron. The working is easily explained: the leaf is introduced between the two cylinders *c* and *c'* the point foremost; it is squeezed, comes up between *c'* and *T* where it is again squeezed, but more strongly. Directly the point arrives at *h* the balance oscillates, the scraper *G'* comes in contact with *T* and the scraping begins, the leaf being retained by *c'*. When the heel is released by *c'* the balance oscillates in the contrary direction, and it is *G* which then comes in contact with *T* and which scrapes the heel, the leaf being then retained by *c''*. When this first leaf is done with, the balance oscillates again, and *G* encounters at *h* the point of a second leaf. And so on. So the leaf comes out completely scraped. The drum *T* and the scraper *G* in effect only form a *Marabal* machine, the cylinder *c''* acting as chop; *G* scrapes in a reverse direction to the passage of the leaf; *G''* scrapes in the same direction as this passage. At the trial of the machine, *G* gave an excellent result, whilst *G'* did not scrape at all; or rather the leaf submitted to the action of *G'* bore a series of transverse scratches produced by the grooves, the skin and the pulp were not raised. This caused the machine to be rejected.

Many other machines, among which those of Messrs. Digard, Carcenas, d'Unienville, &c., may be cited, are the result of patient and laborious researches, but do not yet appear to realize the dream pursued:

In all these machines the end which has generally been aimed at has been to scrape the leaf completely, without having to scrape first one end and then to turn it round to scrape the other end. It is perfectly evident that in that case there would be a less expenditure of workmanship, but would it be worth the trouble? This cannot be done without complicating the mechanism, which ought to be as simple as possible, for it needs great precision, and as was seen above the juice of the aloe attacks iron. The wear and tear produced by these different instruments would without doubt destroy their good working powers. We will consider further on the present machine, whose value consists principally in its simplicity, its easy management, the nicety with which it is constructed, and its moderate price.

The machine sent by M. Paul d'Unienville to the Exhibition of 26th October last is similar to the first one described with this modification, that a "rattletrap" has been adapted to it; the catch and the scraper are identical, except the diameter of the latter which is less being about 1½ foot (fig. 5). A scraper *A* and a catch *S*, that's the old apparatus. At *c* and *c'* two cylinders of wood on smooth cast-iron, turning in the direction of the arrows. At *a* a scraper identical with *A*; *S'* is a joint or catch movable in two slides and which is worked by the hand by means of a lever. The leaf is introduced by the point between *c* and *c'*, the

scraper *A* acts; at this moment *S* is drawn away from *a*; when the heel is about to pass between *c* and *c'*, and at the proper time, *S* is brought back towards *a*, and this applies the heel to *a*, and the scraping is done.

A scrapes then in the direction of the passage of the leaf. It is to be feared that this may be a radical fault and a cause of non-success in the ulterior well-doing of the machine.

In all the machines previously described, it has always been point first by which the leaf has been presented; then the latter was turned that the heel might be scraped. But as the starting-point of all the fibres is precisely in this heel, it follows that only the extremities of the fibres are first scraped, and that in turning the leaf round they are not all laid hold of, and that those which are not secured escape and are lost. If on the contrary the heel is first scraped, the extremities remain imprisoned in the pulp of the point and cannot escape, and all the fibres are certain of being seized upon at their source on turning the leaf round to scrape the point. This is an important improvement which has just been introduced into the manipulation, and which increases the return very sensibly. To arrive at this result it was necessary to modify the old machines which were not constructed so that the heel might be scraped first. The new machine is no other than the old pulley with T irons, with the difference that the latter has a diameter of 2 feet (fig. 7); the T irons being 2 inches, that gives an exterior diameter of 2 feet 4 inches. The speed is 500 revolutions per minute, which makes 3,658 feet per minute for the circumference. There are 18 T irons on the scraper; this number is essential, for the T irons must have the width they possess. With a different width the useful effect is no longer the same; this is proved by experience. The drawing represents two of these scrapers mounted on the same axis, and a single governing pulley.

The advantage of this arrangement is to have three floors *A* which allow the shaft to turn round and to prevent shaking by means of a slight wearing-out of the bushes; besides, the wear and tear is less rapid. The drawing only shows one axis with its two scrapers, but it is only necessary to prolong the solid masonry and to lengthen the axis to have as many scrapers as are wanted. On each side of the scraper there is a piece of wood which extends in front. Between these two pieces is the catch which plays a considerable part in the new process. This catch is composed of a piece of wood *b* terminated by a piece of copper *a*; a screw, or, rather, two screws *v* allow the catch to be regulated, that is to say, to draw it from and towards the scraper, for the catch is supported by two T irons *c*. The regulation once established, this catch is firmly fixed, so as to avoid even the smallest oscillation; it is in this regulation that lies, if not the whole improvement, at least an essential part of it. The piece in copper is the chief point; here is an enlarged representation of it (fig. 6): it has $2\frac{1}{2}$ inches of thickness and it is cut according to the shape *cabd*; *ca* and *bd* are curves adopted by experience. *ab* is a straight piece of $\frac{3}{4}$ of an inch, which is the scraping surface. The edges *a* and *b* must be exactly parallel to the scraper, and as close as possible. If the width is too great the fibres are seized violently and broken, the leaf escapes from the hand which presents it; but if, on the contrary, the regulation is good, a child can present and withdraw a leaf without great effort and without breaking the fibres.

The improvement consists then:—

1st. In the small diameter of the scraper, which permits of its being made of cast-iron, whilst formerly it was of wood.

2nd. More precision in the taking up.

3rd. A catch having scarcely $\frac{3}{4}$ of an inch of

scraping surface instead of 4 inches as formerly, and made of hard cast-iron instead of soft wood.

4th. Finally, and above all, the possibility of scraping the heel of the leaf first.

It must be remarked that all these machines are built on the same principle, which is to scrape the leaf of the aloe with grooves by pressing it against a hard body, which is the "catch." The scraper acting only on one side cannot then scrape but this one side; it is in the backward movement of the leaf, and by the pressure against the servante that the other side is scraped. This is very crude.

All the experiments up to date have been carried on upon a certain plan of machine, none has had for its aim the scraping of the two faces simultaneously, at least no result in this direction is known.

The problem remains then for the experimentalists of the future.

REGIS DE CHAZAL,

Engineer of Arts and Manufactures.

[In view of the admitted imperfection of the machines, we have not reproduced the diagrams. There may be better appliances now employed in Mauritius, and there may be aid given to the extraction of fibre from aloe leaves by the result of the competition which takes place this month in Paris, of machines calculated to deal with stalks of rehea or ramie.—Ed.]

MUDAR.

By W. A. JAYESINGHA,

District Medical Officer for Balangoda, Ceylon.

Calotropis gigantea (R. Brown) is a tree or a shrub growing to a height of about 15 or 20 feet, belonging to the natural order *Asclepiadiaceae*, growing almost all over the island, especially in the hotter parts. It is known in Sinhalese as Wara, in Tamil as Yarrakum, and in Hindustani as Madar. The parts used in medicine are the root, bark, and the milk, obtained by making incisions into the tree.

Dr. Waring in his "Bazaar Medicine," gives the following directions for the preparation of the root:—"The roots should be collected in the months of April and May from sandy soils, and all particles of sand and dirt having been carefully removed by washing, they should be dried in the open air, without exposure to sun until the milky juice contained in them becomes so far dried that it ceases to flow on incisions being made. The bark is then to be carefully removed, dried, reduced to powder, and preserved in well-corked bottles."

Dr. Ainslie, in "Materia Indica," says "that the milky juice of the plant when carefully dried has powerful alterative and depurative effects, and is infinitely more efficacious than the dried root bark."

The root bark and the juice of this tree have for many centuries been held in high esteem by the natives of India as emetic, purgative, and diaphoretic. Dr. O'Shaughnessy, who made extensive trials of the root, has formed a high estimate of its value; according to him, in doses of 30 to 60 grains, it proves emetic after an interval of from 20 to 60 minutes, generally causing much nausea, and in about one case out of three inducing cathartic operation; in doses from 2 to 5 grains every half hour, it proves nauseant, diaphoretic, and after several doses, gently cathartic; on the whole he considers it an excellent substitute for Ipecacuanha.

Drs. Playfair and Robinson, speaking highly of its efficacy state that "in early stages of leprosy, before the eruptions become pustular, there is no medicine from which more benefit is to be obtained than this."

In secondary syphilis, Dr. Robinson regards Mudar as a highly valuable remedy where mercury has been extensively employed; under its use the general health becomes improved, ulcers heal, and blotches from the skin disappear. In dysentery it has been highly spoken of; in severe cases large doses from 20 to 60 grains are recommended for adults. In the Bengal Pharmacopoeia it is used as substitute for Ipecacuanha in the preparation of Dover's Powder thus:—Powdered bark of Mudar two drachms, Opium one drachm, and Sulphate of Potash eight drachms.

The root bark of this tree was used in the treatment of parangi disease by me in the Civil Hospital, Kurunegala, during the time I was there as assistant medical officer.—Christy's "New Commercial Plants and Drugs."

THE ECONOMIC USE OF BARKS.

How few persons ever give a thought to the sources of supply and the various uses of the different vegetable substances which enter into commerce, or are utilised in different forms. Of the three kingdoms of Nature, the products of the vegetable kingdom are certainly the most important, inasmuch as man may be fed, clothed, sheltered, and kept in health by the materials it supplies him with. And what a wide range of useful products is furnished to commerce by every part of plants and trees—the roots, the stems, and stalks, barks, leaves, saps and other exudations; flowers, fruit, and seeds, all comprise extensive lists, the descriptions and details of which would be interesting and instructive. Let us consider but one of these—the different barks. How important are these, and what employment their collection and distribution afford, and how manifold are their economic uses! For general considerations they may be conveniently grouped into three classes:—1, Those employed for their fibrous nature; 2, those used for colouring and tanning purposes; and, 3, those having medicinal uses. I shall confine myself here to the first class; but it may be well to state at the outset, what is the declared value of those we import, which are considered of sufficient importance to be enumerated in the Board of Trade returns.

The value of our imports last year were:

Cinchona barks	£661,682
Tanning barks	147,107
Extracts for tanning and dyeing	394,774
Cork	718,111
Cinnamon	44,061

£1,965,835

To these we may add by estimate:—

Oak bark, produced at home	£1,200,000
Larch bark " "	200,000

£1,400,000

£3,365,835

This, be it remembered, is exclusive of many minor barks, and only comprises the British trade, irrespective of the commerce carried on in other countries.

It is impossible within reasonable limits to give more than a general brief glance at some of the uses of barks, by different peoples—for different economical and manufacturing purposes.

The inner bark of the Lime, Ash, Elm, and Maple, as formerly used for writing on, whence our word library, from the Latin—*liber*, a book. The strips of bark were rolled up to make them more portable and termed "volumen," a name afterwards retained for rolls of parchment and paper. It is doubtful whether the leaves of Palms and other trees were not used even before the fine layers of bark, for the Roman oracles were impressed on leaves.

The bark of the grey Birch, as well as that of the white Birch, is much used in North America in the manufacture of canoes. These are used by the Indians in navigating the rivers and shallow streams. They are long, narrow, light, and fragile in appearance, but when guided by a skilful hand, are capable of being propelled with great rapidity. Birch bark has been used to fumigate rooms.

The inner bark of the white Birch was formerly used for writing tablets before the invention of paper. With the outer thick coarse layers, houses in Russia, Poland, and other northern countries are often covered, instead of with slates or tiles.

The Kamschatdales chop up the bark with the eggs of the sturgeon, and use it as their ordinary food. An empyreumatic oil is obtained from Birch bark, which gives the peculiar odour to Russian leather.

Allusions to the use of the inner bark of the Himalayan Birch (*Betula Bhojpatra*) for writing on are met with in Indian works 2000 years old. The early Aryans, in their settlements in the Punjab and along the foot of the Himalayas, must have found this material ready at hand, and employed it for various purposes of domestic economy, as well as for writing. At present its use is limited to the lining of boots and shoes, and to writing amulets on, which a

enclosed in gold, silver, or copper beads, and borne on the person as charms against evil influences. For this purpose the bark is held in high esteem, on account of its lasting quality, for though thin and fragile to look at, it lasts for centuries without decay. In one instance a piece of Churja bark about 2000 years old was found in the sanctuary of a Buddhist tope.

Of the bark of the Paper Birch (*Betula papyracea*) canoes are constructed, and it is used in the manufacture of various utensils for domestic use, such as drinking cups, dishes, baskets, and chair bottoms. Touchwood of the best quality is made of it, and the Christian Indian tribes of North America use the bark for paper on which to engrave their syllabic literature, as well as for letter writing.

The bark of the White Spruce (*Picea alba*), being skilfully removed in one piece by the Indians, receives the canoe shape by being skewered together, and stiffened by having a few Willows inserted. It is serviceable for a short period only, heat and cold being alike destructive to this species of craft, by rendering the bark dangerously brittle. Pieces of the bark are used for covering houses, and also by the natives for roofing temporary sheds or cabins.

The bark of the Lime (*Tilia europæa*) when steeped in water soon separates into thin layers, which are employed for making a coarse kind of rope, for a matted shoe, much worn by the Russian peasantry, and also for making the bast mats which are so largely imported from Russia, and which are so extensively used in this country for packing furniture, as well as for gardening purposes, &c. For every pair of shoes the barks of three or four Linden trees are requisite; and though these grow faster as they are cut, yet the consumption is enormous, and the destruction of the trees is in consequence immense. One hundred million of these shoes are stated to be made yearly. When the bark is whole it is employed for roofing, for covering the river boats, as well as for making sledges, carts, boxes, &c. When the bark is in several pieces it is used for matting and bags. That of the young Lime tree is used for making cordage, sandals for the peasants, and all sorts of baskets, &c. More than 1,000,000 trees, it is said, are destroyed annually for the bark manufacture at Viatka alone, and the value of the articles produced exceeds £500,000.

Substantial and useful rope is also made of the inner bark of the Lime tree. The best matting or bast is imported into England. After the Lime the Elm, among European trees, produces a fibrous bark, most tenacious and durable, which is employed to make mats and coarse ropes. The bark contains in its cells an abundant mucilaginous principle (20 per cent.), and about 6 per cent. of tanning, but it is not used for this purpose.

From the boiled inner bark of the Russian Larch, mixed with Rye-flour and afterwards buried a few hours in the snow, the hardy Siberian hunters prepare a sort of leaven, with which they supply the place of common leaven when the latter is destroyed, as it is frequently by the intense cold. The bark is nearly as valuable for tanning as Oak bark. From the inner bark the Russians manufacture fine white gloves, not inferior to those made of the most delicate chamois, while they are stronger, cooler, and more pleasant for wearing in the summer.

In North America from the fibrous bark of the Willow a species of twine is made, which the natives manufacture into nets of great durability. The dead inner bark is mixed with oatmeal in Norway. In Russia and Sweden the bark is used for shoes, buckets, boxes, and for roofing. It is also employed as a tanning substance, and when separated into fibre is woven into cloth.

The bark of the Sinaia or Locust tree, *Hymenaea Courbaril*, of British Guiana, is used in the construction of canoes—or wood-skis, as they are termed.

The bark of the Purple Heart, *Copaifera pubiflora*, is also used for this purpose. Some of these canoes are large enough to carry from twenty to twenty-five persons with perfect safety in smooth water.

The bark of several species of *Bauhinia* have economic uses in India; that of *B. acuminata* is considered a

remedy in cutaneous diseases; that of *B. variegata* is astringent, and employed by dyers and tanners; that of *B. tomentosa* for cordage; the thick bark of *B. racemosa* is used as a slow match; bast and strong ropes are made from the fibrous bark of several of the species, and also from those of *Hibiscus* and *Sterculia*.

In Australia the bark of several trees have been experimented on by Baron Mueller for paper-making. The stringy bark of *Eucalyptus obliqua* is extremely thick and bulky, separates with the utmost facility, and is hence universally used for thatching rural dwellings. The supply is available by millions of tons. It is easily converted into packing, printing, and writing-paper, and may also be employed for mill and pasteboards. The pulp bleaches readily. The paper made from the bark of *E. rostrata* is much coarser than that from the stringy bark, but the pulp may be used as an admixture to that of packing paper and pasteboard or as an ingredient for blotting and filtering paper. The bark from several other *Eucalypts* also make good rough packing papers.

Among savage nations, pieces of bark are piled up to make huts for shelter; and the bark simply beaten forms rude cloth, used as petticoats and other garments. The natives of Port Mulgrave, north-west coast of America, are wretchedly clothed in mats woven with the inner bark of *Cypress*, which is tough, flexible and very soft.

Rolls of bark are worn in the lobe of the ear by the native women of the Anamallys, India.

Curious sacks, made in Coorg from the inner bark of the *Antiaris sacidora*, are used for conveying rice and coffee by the villagers in Mysore.

A kind of cloth is made in India, called Arnul, from the bark of *Celtis orientalis*. The inner bark consisting of numerous reticulated fibres, forms a kind of natural cloth used by certain tribes in Assam.

The inner bark of some of the Conifers contains a fecula which, properly prepared, furnishes when boiled, a very edible broth. The Laplanders are very fond of it. When they prepare a meal of it, they bark the tree all around up to a certain height.

The dried bark of the Dogwood, commonly called Red Willow, was used in Lower Canada for smoking by the Indians before they were supplied with tobacco, and many of them still, from motives of economy, mix it largely with their tobacco.

From the inner bark of the Holly macerated in water and boiled during a long period, birdlime is procured.

The bark of *Careya arborea* serves as cordage, and is used as a slow match for guns in the Northern Circars, India.

Hemlock Spruce bark in Canada is stripped off the trees in long slabs, and answers as a substitute for boards in covering the camps or hovels used by the timbermen or woodcutters when engaged in the forests. This bark is largely employed by tanners in North America.

A curious use of bark is that made in Sumatra of Lawang bark (*Sideroxylon Zwargesi*?) to clear muddy water, so as to render it drinkable; it acts in a similar manner to the clearing nut, *Strychnos potatorum*.

The bark of *Quillaja saponaria*, a colossal tree of Chili, is rich in quinine, and thus valuable for dressing wool and silk. It is much used in France and Belgium, and occasionally appears in commerce here.

There are many other fibrous barks which have a commercial value, such as that of the Mulberry (*Broussonetia papyrifera*), for the paper manufacture in Japan; that of the *Daphne longifolia* and *D. papyracea*, for the same purpose in Nepal; and of *Adansonia digitata*, which has been imported from Western Africa for our own papermills. The curious inner bark of *Lagetta linearis* is tough, but of a fine texture, consisting of twenty or thirty layers, each of which, on being soaked in water is easily separated, and extended or drawn out diagonally exhibits the appearance of a fine net lace, from which it derives the name of Lace-bark Tree. The ladies of Jamaica are exceedingly dextrous in making caps, ruffles, doyleys, fans, and other fancy articles of the bleached bark. Cork and many other fibrous barks have not been noticed in this sketch.—P. L. SIMMONDS.—*Gardeners' Chronicle*.

GROWTH OF POTATOES.

The Potato crop is of such great importance that anything pertaining to it is of interest. Anything, moreover, that can rouse us from the paralysis of routine and do something towards obviating the waste that is the consequence of our neglect and ignorance is worthy of attention. On this account we venture to call the attention of our readers to a very valuable contribution to cultural chemistry that has recently been issued by Dr. J. H. Gilbert, F.R.S., in the form of a lecture delivered at the Royal Agricultural College, Cirencester.

The lecture embraces the results of field experiments at Rothamsted on the growth of Potatoes for twelve years in succession on the same land, with collateral investigations into the composition of the produce, made in the Rothamsted laboratory, together with some results by other investigators.

The Rothamsted experiment consists of ten plots; one has received no manure since the commencement, the others have received various artificial manures or farmyard manure. The variety of Potatoes grown during the first four years was the Rock; subsequently the *Champion* was grown.

The following table gives a summary of the average produce of Potatoes over the total period of twelve years, under each of the different conditions as to manuring.

Manures and Produce per Acre per Annum during Twelve Years—1876-1887.

	Good.		Small.		Diseased		Total.	Per cent. Diseased
	Tons.	Cwt.	Tons.	Cwt.	Tons.	Cwt.		
Unmanured ...	1 13 $\frac{3}{4}$	0 5	0 1 $\frac{1}{2}$	0 1 $\frac{1}{2}$	1 19 $\frac{3}{4}$	3 15	3.15	
Superphosphate	3 5	0 5 $\frac{3}{4}$	0 2 $\frac{3}{4}$	0 3	3 13 $\frac{3}{4}$	3 66	3.66	
Mixed mineral manure ...	3 7 $\frac{3}{4}$	0 4 $\frac{3}{4}$	0 2 $\frac{3}{4}$	0 3	3 15 $\frac{3}{4}$	3 45	3.45	
Ammonium-salts alone ...	1 17 $\frac{3}{4}$	0 6 $\frac{1}{4}$	0 17	2 5 $\frac{3}{4}$	2 12 $\frac{3}{4}$	4 06	4.06	
Nitrate soda alone	2 4 $\frac{3}{4}$	0 5 $\frac{3}{4}$	0 2 $\frac{3}{4}$	2 12 $\frac{3}{4}$	2 12 $\frac{3}{4}$	4 93	4.93	
Ammoniumsalts and mixed minerals...	5 18 $\frac{3}{4}$	0 7 $\frac{1}{4}$	0 8 $\frac{3}{4}$	6 14 $\frac{1}{2}$	6 14 $\frac{1}{2}$	6 26	6.26	
Nitrate soda and mixed minerals	5 17 $\frac{3}{4}$	0 6 $\frac{3}{4}$	0 9 $\frac{1}{4}$	6 13	6 13	7 00	7.00	

These results show that the average produce of tubers over twelve years without manure is scarcely two tons per acre, and it was found that there was a considerable decline from period to period under this exhausting treatment. Nevertheless, this low yield without manure for twelve years in succession on the same land, is about as much as the average produce of Potatoes under ordinary cultivation in the United States, and nearly two-thirds as much as in some important European countries.

By superphosphate of lime alone the produce is raised to nearly 3 $\frac{3}{4}$ tons; and by a mixed mineral manure containing, besides superphosphate, salts of potash, soda, and magnesia, to just over 3 $\frac{3}{4}$ tons, or very little more than by superphosphate alone. It is evident, therefore, that up to this amount of production, the character of the exhaustion induced by the growth of the crop on this land, which was, agriculturally speaking, in a somewhat exhausted condition, was much more that of available phosphoric acid than of potash, or the other bases.

In reference to this increase in weight by mineral manures alone, it may be observed that the result is quite consistent with that obtained with root-crops, having comparatively shallow root development; and in such cases the source of the nitrogen is chiefly the store of it in the surface soil.

It is remarkable that there is much less increase of produce of Potatoes by nitrogenous manures alone than by minerals alone. Thus, with ammonium salt there is an average produce of scarcely 2 tons, 6 cwt., or only about 6 cwt. more than without manure; and with nitrate of soda alone there is an average

of only 2 tons 12½ cwt. per acre. The better result by the nitrate is doubtless due to the nitrogenous supply being more immediately available, and more rapidly distributed within the soil, and so inducing a more extended development of feeding roots.

These negative results by the nitrogenous manures alone confirm the conclusion that by the continuous growth of the crop on this land it was the available supply of mineral constituents within the root-range of the plant, more than that of nitrogen that became deficient.

The last two lines of the table show, that with a combination of minerals and nitrogenous manures there was an average of nearly 6½ tons per acre, which is higher than the estimated average produce of either division of the United Kingdom; and more than one and a half times as high as in Ireland in recent years. These results may be taken as fairly indicating the characteristic manurial requirements of the crop, and that both mineral and nitrogenous manures are required to give full crops.

The last column shows the average percentage of diseased tubers under each of the several conditions of manuring. It may be seen that, without manure and with purely mineral manures, the proportion of diseased tubers is much less than where nitrogenous manures were applied. Consequently, with luxuriance of growth and high produce, the disease is most prevalent.

A point of considerable interest was brought to view in the fact that there was, under every condition of manuring, a very much larger proportion of diseased tubers over the first four years, when the Rook was grown, than afterwards with the Champion. The very bad result over the first period was, however, doubtless in great measure due to the character of the climate also, which included some exceedingly wet and unfavourable seasons.

“PRODUCE WITHOUT MANURE, AND WITH FARMYARD MANURE.”

The following table shows the average results (per acre per annum) for each of the farmyard manure plots, compared with that of the unmanured plot, over the whole period of twelve years, 1876-1887.

	Good.		Small.		Diseased		Total		Per cent
	Tons.	Cwt.	Tons.	Cwt.	Tons.	Cwt.	Tons.	Cwt.	Per cent.
Unmanured —	1 13½	0 5	0 1½	1 19½	3.15				
Farmyard manure, six years; unmanured, six years — —	3 12½	0 6½	0 3½	4 2½	4.56				
Farmyard manure and superphosphate, seven years; farmyard manure alone, five years —	4 7½	0 6½	0 4½	4 18½	4.93				
Farmyard manure, superphosphate, and nitrate of soda, six years; farmyard manure alone, six years* — —	4 15½	0 6½	0 9½	5 11½	8.82				

Comparing these results with those obtained by artificial manures alone, we find that farmyard manure, which, besides an abundance of mineral matters, and a large amount of organic substance rich in carbon, supplied annually about 200 lb. of nitrogen—gave considerably less produce than an artificial mixture of minerals and ammonium salts of nitrate of soda, supplying only 86 lb. of nitrogen per acre per annum. The fact being, that it is only the comparatively small

* The superphosphate, but not the nitrate, was applied in the seventh year, 1882.

proportion of the nitrogen of farmyard manure which is due to the liquid dejections of the animals that is in a readily and rapidly available condition, while that due to more or less digested matter passing in the solid matter, is more slowly available, and that in the litter remains a very long time inactive. Hence, the addition of nitrogen, as nitrate of soda, to the farmyard manure had a very marked effect.

It may be mentioned that, over the last six years, farmyard manure, together with the residue of previously applied farmyard manure, superphosphate, and nitrate of soda, only yielded an average of about 4 tons of tubers; and that farmyard manure and the residue of farmyard manure and superphosphate, only gave about 4½ tons, whilst farmyard manure alone gave, over the first six years, 5½ tons, is a clear indication that the later seasons were somewhat less favourable for luxuriance with such manures.

The last column of the table shows, as before, that the proportion of diseased tubers was the greater, the greater the amount of nitrogen supplied, and the greater the luxuriance.

The next point of interest is the amount of some of the more important chemical constituents of the tubers stored up in the crop, under the influence of the different manures, and especially the increased amount for a given quantity of nitrogen supplied in manure.

The average amount of nitrogen annually stored up in the tubers grown without manure was, notwithstanding the amount supplied in the seed, only 14.9 lb., or less than would be yielded in Wheat or Barley under the same conditions.

On the other hand, the direct application of 86 lb. of nitrogen per acre per annum, in the form of ammonium salts alone, only raised the amount taken up to 19.7 lb., and when supplied as nitrate of soda alone, to only 23 lb. The incapacity of the plant to avail itself of the supplied nitrogen in the absence of a sufficient available supply of mineral constituents, is thus strikingly illustrated.

With the same applications of nitrogen, but in conjunction with the mixed mineral manure, the amount of nitrogen stored up in the tubers is raised from 20 lb. to about 50 lb.

It is remarkable that, by the use of superphosphate alone, 30 lb. more potash are taken up per acre than without manure, and that only 3 lb. more are taken up under the influence of minerals alone, which, besides superphosphate, supplied annually nearly 150 lb. of potash. It is well known that one special effect of superphosphate applied to spring sown crops, is greatly to increase the development of feeding-root within the surface soil; and thus it would seem that under its influence, probably on both soil and plant, the Potato has been enabled to obtain a large amount of potash from the stores of the surface soil.

It is, however, when the mineral and nitrogenous manures were supplied together, that the greatest amount of potash is taken up. Indeed under the influence of this combination, nearly one-half of the 150 lb. of potash annually supplied is recovered in the increased produce.

But little is definitely known of the special function of individual mineral constituents in vegetation. It is, however, pretty clearly established that the presence of potash is essential for the formation of the chief non-nitrogenous matters—starch and sugar; and here in the Potato we find a greatly increased amount of potash in the heaviest crops, that is to say in those in which the largest amounts of starch have been formed.

In regard to the application of farmyard manure for the Potato crop, the results seem to indicate that this plant is able to avail itself of a less proportion of the nitrogen of manure than any other farm crop. Yet, in ordinary practice, farmyard manure is not only largely relied upon for Potatoes, but is often applied in larger quantity for them than for any other crop.

It is probable that, independently of its liberal supply of all necessary constituents, its beneficial effects are in a considerable degree due to its influence on

the mechanical condition of the soil, rendering it more porous and easily permeable to the surface roots, upon the development of which the success of the crop so much depends. Then, again, something may be due to an increased temperature of the surface soil, engendered by the decomposition of so large an amount of organic matter within it; whilst the carbonic acid evolved in the decomposition will, with the aid of moisture, serve to render the mineral resources of the soil more soluble.

The Potato is, indeed largely a kitchen and market garden crop, as well as a farm crop; and for the production of garden vegetables generally very much larger quantities of farm or stable manure are applied, beyond what is required as a mere supply of constituents to the crops, the process being to a great extent one of forcing, and a necessary result is a great accumulation of unexhausted residue within the soil.—*Gardeners' Chronicle.*

INSECT PESTS OF THE TEA PLANT.

Since tea has now become the principal staple in Ceylon, I have thought that some account of the insects affecting this product may be of interest to Ceylon Planters. I have for several years been observing the habits of the insect friends and foes of the tea plant, and I now propose to give a series of articles describing the life-history and habits of the different species that have come under my observation, (to be illustrated if possible with simple diagrams and sketches.) These notes will not be arranged in any definite order, and will be supplemented from time to time by any further information, I am able to obtain. The list will contain any insect that derives its living from the tea plant, whether its attacks are extensive enough to materially affect the growth of the plant or not; but at the same time such fact will be duly noted.

I shall be very grateful to any one who will assist me with specimens, observations, or statistics relating to this subject. This is the more desirable as different districts are frequented by different species.

Eumeta cramerii.

- a. Larva
- b. Perfect insect, male
- c. Perfect insect, female

No. I. THE FAGGOT-WORM, *Eumeta cramerii.* Before the introduction of tea this insect was commonly found on coffee, where it did little or a

damage. At present, if it would confine itself to well-established trees, it would be of little consequence. But the larva (*fig. a*) has a habit of billeting itself upon some young plant, and not only devours the leaves but cuts off the woody shoots for building purposes.

A glance at the figure will show that the caterpillar is enveloped in a case composed chiefly of twigs arranged side by side around its body, forming a faggot-like bundle which has given to allied species in other countries such names as the 'lictor'—'faggot-worm'—and 'basket worm.' The twigs are held together by a firm and tough lining of silk. This case is a very effective protection to the soft body of the grub. The head and front part of the body, which alone are extended while the animal is travelling or feeding, are strengthened by horny plates. The hinder part of the body is soft and fleshy and always remains hidden within the case; the legs on this part are undeveloped, being represented in a very rudimentary condition as small hooks, serving to fix the insect into its case. The silk lining of the case is continued for a short way in front as a soft flexible tube to enable the larva to move its head freely in search of food; and when the animal retreats inside, this part is drawn down after it to close the opening.

When the young larva is first hatched from the egg it is of course unprovided with any covering for its body. It crawls about on its front legs, with the hinder parts elevated, looking for building material. It commences modestly with small fragments of leaves or atoms of bark, and gradually enlarges and extends its habitation as it grows: the twigs are added one by one as the animal finds itself strong enough to bear their extra weight. Like all other caterpillars, this species is subject to periodical moults; these it undergoes within its case, having first anchored it to a leaf or branch of the tree. On the last of these occasions, when it is about to change into a chrysalis, it fastens the upper end of its case very firmly to the support and securely closes the opening; it then turns round so that its head rests near the opposite and lower end which is still open, and in this position becomes transformed into a chrysalis.

After some weeks' time the final change occurs, when the male emerges as a moth (*fig. b*) with a very hairy body and delicately feathered antennæ. Its wings are dull brown with darker veinings on the front pair.

The female is not so fortunate. Her last stage (*fig. c*) is a distinct retrogression. She has neither eyes, antennæ, wings nor legs; nor even a mouth, for in this stage she takes no nourishment; she is in fact little else but a mishapen bag of eggs. The head and front part are protected by reddish horny plates, while the rest of the body is of a pale cream colour with the exception of two brownish downy patches near the end. This extraordinary creature remains for the rest of her life hidden within her case. Here the eggs also remain until they are hatched, which takes place after the death of the parent, and in some species the young are said to make their first meal off her shrivelled body.

The female being a larger and heavier insect than the male, inhabits a larger faggot of sticks. One of these in my collection measures two and three-quarter inches in length, with a circumference of nearly two inches, and bears sixteen pieces of twigs, which represent about forty inches of tea stem—rather a heavy tax upon a young plant.

Fortunately they are not known to occur in any great numbers. Should it be found necessary to destroy them, hand picking would be the only remedy. They are so well protected they fear few natural enemies, but, in common with every other caterpillar, they are doubtless subject to the attacks of internal parasites.

The moth—the male insect—is rarely seen, and the large female cases are much more common than those of the male: it is therefore probable that, as in several allied species, the young are produced for several generations by parthenogenesis.

The natives have a quaint legend concerning these insects. The story goes, that in a previous life they existed in a human form, when amongst other crimes they made a regular trade of stealing firewood: at

their death their souls were sent into the bodies of insects and condemned to perpetually carry about with them a faggot of wood.

The figures in the illustration are drawn of the natural size.

E. ERNEST GREEN.

Eton, Ponduloya, 24th June, 1889.

—“Ceylon Independent.”

THE JOKAI (ASSAM) TEA COMPANY, LIMITED.

Capital £250,000, in 25,000 shares of £10 each.

The ninth ordinary general meeting of shareholders was held on Monday at the registered office of the company, 14, St. Mary Axe, Mr. J. Berry White, the chairman of the company, presiding. The Chairman said:—

CROP ESTIMATES.—The estimates for next year's crop, as received from the several divisional managers point to a yield of two and a half million pounds of tea, to cost 7½d per pound laid down in London, including sale charges. These estimates, I feel sure, will prove as they have always done in the past, to be the minimum of yield and the maximum of cost. It is quite right and commendable that the managers should err on the side of caution, but I am very certain that the results will be considerably better. Last year I took the responsibility of telling you that the outturn would be at least two millions, although the estimates were only for one and three-quarter millions. Again I venture on the dangerous field of prophecy, and assure you that I will be greatly disappointed if the crop is not nearer three than two and a half millions, and that the cost of production will be under 7d per lb. If it sells for 9d per lb. gross—a rate which provides for a further fall in the tea market—we will be able to continue the customary dividend, and also place a respectable sum to reserve, as 1d per lb. is equivalent 5½ per cent on our proposed capital.

THE FALL IN TEA.—The fall in the market value of tea has made a terrible difference to us on the year's working. When we issued our interim report in December last our average sale price was per lb. 11½d, so that if we had maintained that rate our net profits would have been exactly £15,500 more, or nearly equal to 10 per cent on our capital. I greatly fear that we will never see an average of 1s, or even of 10½d per lb. again. We have still 100 millions of lb. of Chinese tea to displace, and while the struggle continues it is hopeless to expect any improvement in prices. On the other hand I do not anticipate any further material drop. Putting the Chinese competition out of consideration, there is no doubt that more than 50 per cent of all the tea exported from India and Ceylon cannot be sold on this market for 8d per lb. without serious loss to the growers, and people will not continue a hopeless contest for any long time. But while I do not expect any recovery in values, I am hopeful that our profits in this company in future will not be less satisfactory than in the past, and I look for such profits in the direction of still further reduction in the cost of production. This reduction cannot be attained by penurious economies or petty savings.

ECONOMIC WORKING.—Our marked success so far has been due to a very liberal outlay judiciously expended. A great deal of our past expenditure has been made with an eye to the future. We have not only made large extensions to our block, but have spared nothing in the general improvement of the estates. We have laid out large sums upon drainage, upon wire fencing, on all the newest types of labour and fuel-saving machinery, upon substituting permanent for temporary buildings, and all such outlay has been charged to the revenue of the past few years. If we found it necessary to curtail this sort of expenditure and work purely on revenue account, I am convinced that we could place our teas in London for 5½d per lb. Indeed, this has been proved by the working of the Jamira division last season. If you will turn to the accounts, you will see that the tea cost less than 4½d per lb. f. o. b. in Calcutta, and adding

2d from there, was put down under 6½d here, and in addition 156 acres of young plants were either planted or kept up, being more than a fourth of the whole. If Mr. Hainworth, our excellent manager there, had only his full-bearing plant to work there can be little doubt that the cost could not have exceeded 3d per lb. in Calcutta and 5d in London. What Jamira has done, all the other divisions are capable of doing whenever called upon. With the advantages we and our neighbours in the Luckimpore district—the natural home of the tea plant—possess in riches of soil, congenial climate, and railway transport, giving returns of from 600 to 840 lb. per acre, we can look forward to the future with assured confidence that notwithstanding the opening out of new tea districts, our position is absolutely unassailable. (Cheers.) Gentlemen, I now beg to move that the report and accounts be received and adopted.

Mr. TYE asked whether the chairman could give any information regarding Ceylon tea.

A SHAREHOLDER: I suppose the railway will eventually effect a considerable saving?

The CHAIRMAN stated that he anticipated a very considerable saving. He went on at some length into calculations and facts connected with the manufacture of Ceylon tea, and pointed out that labour was dearer, that rice, ghee, and dhol were dearer, and that on many estates in Ceylon the soil was not so favourable for tea cultivation as in Assam. No doubt the enterprise of the planters in Ceylon would, in time, lead them to substitute the cultivation of some other plant for tea.

In reply to a further question,

The CHAIRMAN said the directors did not anticipate the slightest difficulty with regard to labour on the company's gardens. The gardens had a good repute, and many of the men recruited the number of the labourers from amongst their own friends. (Hear, hear.)—*H. and C. Mail*, June 21st.

COCONUT PLANTING—RAJAKADALUWA, CHILAW, July 9th.—Coconut clearings looking *A I* on my return from a brief holiday, despite an unusually short rainfall for the month and a very stiff south-west wind which, blowing continuously, tried the young plants a good deal. Coconuts everywhere round about are looking very well, and my 3½ year old tree with crop is a nine days wonder in the district. A plantain monstrosity on Toynbee has appeared. The tree, beside bearing its fruit in the ordinary way, has 4 branches growing from the root, similar to the racemes of a cardamom bush.

CORK.—The “Educator” says:—There are but three countries where cork can be successfully cultivated—namely, Spain, Portugal, and the north of Africa. The cork oak does not attain a great size, usually being only from twenty to forty feet in height. The cork is of very slow growth, and the trees are from twenty-five to thirty years old before the first bark can be removed. This bark is called “virgin cork,” and it is used in ferneries, conservatories, and for ornamental work in gardens. This outer bark has to be removed carefully so as not to injure the inner layer of spongy tissues which will produce the white bark out of which bottle corks are made. The second bark takes from eight to ten years to mature in Portugal, and two or three years longer in Spain and Algeria. The season for gathering the bark is from May to September. The bark is cut in a circle around the trunk or limb, and then longitudinal incisions are made to the desired depth with a circular knife having two handles. The bark is then loosened, stripped off, and afterwards gathered into heaps and taken to the factories, where it is soaked in water, scraped, boiled for a few moments in caldrons, and then dried and pressed into a flat shape. Healthy trees will usually continue to yield bark from 100 to 150 years. The process of peeling the trees is repeated at intervals of from six to eight years.

COTTON CULTIVATION IN CEYLON.

In our Agricultural Review preceded to the "Ceylon Handbook and Directory," a concise summary is afforded of the past history of cotton—both cultivation and manufacture—in Ceylon. It ought not to be a matter of surprise that so little attention was given during our prosperous coffee era, to cotton any more than to other new products. So long as coffee continued a profitable investment, neither planter nor merchant cared to be troubled with anything else, whether cotton, tea, or even cinchona or cardamoms. It is for instance a most remarkable fact that not even in the crisis created by the great American War from 1861 to 1864, and the scarcity of the raw material which led to the Lancashire famine, and attracted the attention of the civilised world,—that not even then did a Ceylon merchant or planter engage in the cultivation of what was by far the most valuable raw product of that day. Of course there was at first the anticipation that the blockade of the Southern States might be effectually broken and the cotton stores let loose; while later on, India did a great deal by extended cultivation to supply the cotton deficiency. Nevertheless, when we recall the fact that within twelve if not six months in 1861-62, "Tinnevely cotton" had risen in price from 2½ to close on 1s 6d a lb. and the great fortunes which were cleared by several Colombo merchants, it is very extraordinary that more was not made of such capabilities as the island possessed for the production of cotton. It was generally received as correct at the time that the chief partners of Messrs. C. Shand & Co., Darley, Butler & Co., Alstons, Scott & Co., and J. C. Fowle,—all Colombo mercantile houses in the Tinnevely cotton trade,—cleared from £20,000 to £60,000 each by "cotton" within a short period, and yet not one of these gentlemen so far as we know, invested a rupee in the cultivation of the plant in Ceylon. "Coffee" alone engrossed attention, Mr. Alex. Gibson, for instance, putting much of his surplus profits into the series of Haputale coffee estates which gave him such splendid returns for many years; and indeed it could very well be urged at the time that as labour was only too scarce for the recognised staple product of the island, there was none available to engage in a new and untried article like cotton.

At the same time it could not be said that it was for want of information as to the capabilities of Ceylon that nothing was done in the "sixties." We have before us, as we write, a copy of a "Report on the Present Condition of Cotton Cultivation in Ceylon with Suggestions for its extension and encouragement by James Augustus Caley, F. R. S.," printed at Manchester in 1859. That was two years before Abraham Lincoln's election started the great Secession War across the Atlantic. Mr. Caley was an officer of our Public Works Department and his report was drawn up at Peradeniya in April 1857. We are not going to extract from it today, further than to say that Mr. Caley anticipated great results for Ceylon and its people from the systematic cultivation of cotton by European capitalists. He pointed out fairly enough that although the natives grew coffee before the European planter came, yet it was only the example and stimulus of the latter which led to the development of the native coffee industry and an annual crop worth R5,000,000. In the same way Mr. Caley argued that if once a start were given to "cotton," a national industry would be developed of far more importance to Ceylon than ever coffee could be. For, not content with a report and practical notes on the cultivation, the valuation

of samples already produced, the character of the soil required, how to separate the seed, &c., Mr. Caley presented his readers with an elaborate table showing the "Cotton-growing districts in the island of Ceylon" giving a large amount of information under a series of useful headings for each of the six provinces, but more particularly for the Northern, Central and North-Western Provinces. This was still further illustrated by an approximate sketch map of the cotton producing districts with indications such as only a road officer could afford, to represent the method of drawing the produce to the coast. In this way, Puttalam, Chilaw and a point between Kalpitiya and Mannar were to become great cotton ports; while Hambantota and Batticaloa were not to be left far behind. Alas, for anticipations never realised! And yet Mr. Caley was able to show that an annual crop of about 150,000 lb. of cotton was produced in Ceylon thirty years ago, and that in the Jaffna district alone there were nearly 1,000 weavers fully employed. We mention so much in connection with Mr. Caley's tabulated information, from which we may make extracts later on, and we certainly trust that the interest lately taken in establishing a cotton-growing industry will not subside until we are assured that for natives,—if not for European planters,—the cultivation has become an important addition in many districts, to existing means of subsistence. At the same time we hope "the battle royal" will not prevent a good many planters as well, from following the example of Mr. Blackett and giving the product a fair trial as an auxiliary, if not a principal article of culture.

COTTON:—MR. CALEY'S REPORT ON
COTTON CULTIVATION IN CEYLON.

The more we examine this document, the more are we impressed with the value of the information collected by the able Manxman who once adorned the ranks of the Public Works service of Ceylon. Mr. Caley was a meteorologist as well as a geologist—an amiable and accomplished gentleman and an honest public servant. From his notes we see that cotton flourishes in India in a dry and even an arid climate and our remarks recently on the rainfall map of Ceylon showed what an enormous proportion of the island is distinguished by such a climate. Largely co-extensive with this climatic zone (or zones rather, in the North-west and South-east of the island) is the occurrence of a coral and shell breccia, which, judging from the analysis of the Indian regur soil, is especially adapted for the growth of cotton. Those who meditate trying the cultivation must not forget that, besides the crop of wool, the seed is valuable for cattle feed, simply crushed and expressed into oil and manurial poonac. The stalks too are good for manure and fuel and have recently been found to yield a good fibre. On unirrigated soil in a dry climate, well cultivated cotton ought to yield 150 lb. per acre of wool. Irrigated, the produce ought to be at least doubled; and if it is objected that the tanks have been constructed and restored specially for the production of rice, the answer is that food grains and cotton can well be grown together and harvested in succession. In Mr. Caley's time, 1857, there was no idea of local demand for a local manufactory, and so he contemplated Ceylon growing cotton to be absorbed into the Tuticorin market! The very opposite process is likely to take place, unless, as we hope, local growth, under the encouragement now offered, —seeds of the best varieties being provided and

all possible information furnished,—should not only meet but far exceed local demand. Europeans now enjoy fair health in the north-central, eastern, northern and south-eastern portions of the island, where the climate and soil specially favourable to cotton cultivation exist. It is quite possible therefore, that Europeans could personally superintend cotton cultivation on a large scale in the dry and arid regions. In any case they could visit and direct such cultivation so as to ensure all possible success. We are aware, from personal observation, that experiments made in the Jaffna Peninsula now nearly half a century ago by the Messrs. Whitehouse Brothers and Mr. Hardy, were not successful. But prices are now better and the cultivation better understood. There is far better soil on the mainland than that in which the experiments were conducted in the Jaffna Peninsula,—in the north-central Province certainly. There the difficulty is population, but as Jaffna Tamils are flocking in to cultivate rice, so Tinnevely and Madras Tamils might be induced by liberal offers of land to emigrate for the cultivation of cotton, alone or as a mixed crop with food grain,—on unirrigated soil or on land “under” tanks,—we cannot help thinking that irrigation in dry or arid regions would obviate all difficulties as to boles forming in the monsoon rains and also enable the cultivator to set insect and other enemies of the crop at defiance. But any way, now that a large local demand and fairly remunerative prices are assured, we feel certain that the vaticinations of Mr. Caley and others as to Ceylon becoming a considerable cotton-producing country are likely to be fulfilled.

THE FUTURE OF CEYLON TEA IN THE LONDON MARKET.

At a time when the long-continuing fall in the price of our teas at home was creating a well-founded alarm among the proprietors of estates, it would certainly have been cheering to have learned that the opinion of Mr. Roberts, of Messrs. S. Rucker & Co., the well-known and highly reputed London firm, was to the effect that the lowest point of fall had been reached and that an upward tendency in prices might shortly be looked for. That opinion, it will be observed, was expressed to our London Correspondent on June 28th when the average for Ceylon teas had reached the lowest point of 8½d. And now that the reaction has set in and the average has risen to nearly, if not quite 10d, full credit should be given to Mr. Roberts. Our London Correspondent has been favoured by this gentleman with his views on the subject of our teas ever since their cultivation on any large scale commenced in this island, and it may be stated as a fact that Mr. Roberts' anticipations have uniformly been fulfilled. It was Mr. Roberts who, at the time when nearly all the London houses refused almost to look at Ceylon teas, asserted his belief in the great future that lay before our now chief local industry. He recognized in the overburnt and crudely prepared tea that was then shipped from this island, qualities which he felt assured must, when the preparation was better understood and practised, certainly give to Ceylon teas the pre-eminence in popular favour which they have since obtained among the tea-drinkers of Great Britain.

But apart from the wide experience and highly trained judgment which enabled Mr. Roberts to express himself with such confidence, he is possessed of an exceptional position which should

render any opinion he may form exceedingly reliable. As a member of a firm largely engaged in wholesale dealings in tea of all growths and descriptions, no one can be better qualified to estimate the position and prospects of any special production; while the further fact that, as being connected with a Company whose main function is the distribution of Ceylon produce to the retail dealers of the United Kingdom, it must be to his interest to be able to purchase our teas at the lowest possible rates, lent force to the view expressed by him that the term of capability to purchase at recent low prices was coming to an end. For these several reasons, therefore, we are fully prepared to endorse the confidence expressed by our London Correspondent as to the value attaching to any judgment so experienced an expert and distributor as Mr. Roberts may enunciate. We have but recently referred in our editorial remarks to the points raised by Sir Robert Hart in his official report on the tea trade of China. It will be observed how strongly Mr. Roberts adopts the views we have ourselves expressed that it is impossible, on Sir Robert Hart's own showing, that the competition of China in the English tea market can be much longer continued. If the conclusions of so experienced a local official as expressed in that report may be accepted—and there is every reason why reliance may be placed upon them—every pound of tea now sent home from China, is being supplied at a dead loss. The result we have seen apparent in the large diminution that has now gone on for successive years—and especially during the present season—in the shipments made from the Celestial Empire to Great Britain, and it appears certain that the causes which have brought this about must be equally operative to “hasten the end.” We have before detailed our reasons for believing that the only recommendations apparent to Sir Robert Hart whereby this diminished shipments may be stayed are impossible of being carried into effect, and we need not therefore now further refer to them. But we may be fairly well assured that as prices now rise, the teas of Ceylon and India will be forwarded in quantities which will maintain values at a level equal, we trust, to affording an adequate return to the planters, while still offering an effective bar to the resuscitation of Chinese competition.

There are several other points in Mr. Roberts' interesting and valuable remarks to which the attention of our upcountry readers may well be directed. We have before been favoured with his views as to the desirability of medium plucking, and have learned how strongly he would deprecate any attempt to confine our harvesting, preparation and exports wholly, or even nearly wholly, to the higher grades of tea. To do this would, in his opinion, tend seriously to narrow the field within which the taste for Ceylon teas can be cultivated among the tea-drinkers of the United Kingdom; but in the remarks with which we have now been favoured Mr. Roberts includes the observation “But pray don't sacrifice quality”; that is by overstrained and injudicious attempts to economize in the cost of production and preparation. It is certain from what we read in our London Letter that Mr. Roberts would urge upon our planters to abstain from sending home any great bulk of what may be termed “inferior teas,” though he would desire to see a certain proportion of second, and even third, class teas accompany those of the finer pickings. He condemns the large amount of “simultaneous arrivals,” manifestly of inferior qualities, which flood the market and find but few buyers willing

to burden themselves with an excessive proportion of teas of that class. There ought to be no difficulty by wisely concerted action among ourselves in obviating the continuance of this obstacle to free sale, one which Mr. Shand has but lately also strongly condemned in his speech to the members of the Ceylon Association in London as mainly contributing to keep down prices. Mr. Roberts evidently thinks that the remedy for present evils lies largely in our own hands; and, aided by the efforts making by our representatives at home, there can be no reason why we should not successfully adopt it. Indeed the conclusions arrived at by Mr. Roberts on a former occasion, and repeated very much at present, coincide exactly with the opinions of the large majority of our most experienced, careful planters who will have no more to do with so-called "fine" than with "coarse" plucking of their tea-leaf, but who believe thoroughly in "medium" plucking giving such a proportion of the lower grades of tea as Mr. Roberts—in contrast with some other London would-be authorities—considers to be right and natural. The low average established for Ceylon teas by the present mail, caused by the cheapness of pekoes and souchongs, induces a local revival of the advice to do away with the "inferior grades"—and then how good an average could be established! No practical planter can, of course, accept such a view of the situation; while Mr. Roberts would be the first to call out that we were distinctly and deliberately playing into the hands of the China dealers. Let our planting readers note what is said in another place about the stock of tea at Foochow being "300,000 chests, half of which is only worth 4d in London." By plucking "fine" and sending home only the higher grades—if that were possible—we should soon make an opening for every chest of the Foochow fourpenny tea in London.

CEYLON TEAS IN THE UNITED KINGDOM.

(From our London Correspondent.)

MR. ROBERTS (OF S. RUCKER & CO.) ON CEYLON TEAS: GOOD PROSPECTS.

LONDON, June 28th.

You will readily understand that the alarm finding expression in your columns in consequence of the constant fall in the price of tea in the London market has found a serious echo among Ceylon men now at home. Even the most hopeful of these with whom I have discussed the matter have confessed that the outlook was a grave one, and under such conditions it appeared to me most desirable to ascertain the views entertained on the subject by Mr. Roberts of Messrs. S. Rucker & Co., whose opinion have so often been quoted by me, and which have on several occasions received full confirmation by after events. There is no one among the experts to whom it is customary for me to resort, when questions connected with Ceylon matters arise, as to which it is desirable for me to obtain the *dicta* of such well-informed and competent persons who is more willing than is Mr. Roberts to oblige me to the full extent of his power, and my obligations have repeatedly had to be gratefully expressed to him for his great kindness. On the last occasion of the kind therefore, viz. when within the last few days I once more resorted to "my guide, master and friend" on the subject of teas, I found him as usual most ready to bid me. Placing before him fully, and in as much detail as was at my command, the situation in which Ceylon tea planters find themselves as the result of the depressed price of their product, Mr. Roberts offered me in substance the following reassuring remarks:—"I am sorry to see people in Ceylon take rather a

gloomy view of tea, as I gather from what you have mentioned to me. I do not think you will have Ceylon teas lower; I fancy we have seen the lowest. It has only given way in price owing to simultaneous arrivals; but we cannot get over the positive fact that day by day, the public are getting to appreciate more and more the quality of Ceylon tea as being far superior to China and even the bulk of Indian, and they reject these for Ceylon, a fact which must tell in time. The difference between the price of China and Ceylon will not stand in the way of consumption. *Shopkeepers* mix common China and strong Indian teas so as to get a larger profit, but the price they sell at to do this is only a shade under Ceylon, on which they do not get so much profit: but loads of other channels, besides the ordinary shopkeeper are springing up and introducing Ceylon tea in a more direct form from producer to consumer, by which means the consumer can get this better article at the same price as the inferior mixtures sold by most shopkeepers; and the public taste will learn, and is learning, to taste the better article, and the more there is to handle and deal with, the more chance there is to get it into more general consumption. Besides all this, China at its present price is, I hear, losing quite sixpence per pound—and if even only fourpence—it is not likely that the shipments from that quarter will increase. Give the public China and India mixed, and charge them 1s 6d per pound and Ceylon at 1s 9d per pound: the public will prefer to pay 1s 9d for the better article; and a retail price of 1s 9d per pound to the public means 10 pence in bond for Ceylon. This is just a rough way of putting it. I have every confidence in Ceylon keeping up and even improving in value. Every economy must be used in the island to keep down expense, but pray don't sacrifice quality." Remark in addition to what Mr. Roberts has said by myself would be, of course, superfluous. You should, however, bear in mind how great are his opportunities for forming a reliable judgment, and how constantly his views have been substantiated in the past. Those to whom these views of his have been mentioned by me acknowledge the good reason there is to found hopefulness upon that gentleman's conclusions. It is natural, of course, that the shoe should pinch you in Ceylon at present rates, but these are not so hopelessly low as to deprive your planters of some profit, even if this be somewhat unpleasantly restricted; while they must tend in a far greater degree to break down the success of that competition to which you are at present exposed. Reading Mr. Roberts' remarks by the light of what Sir Robert Hart has but recently written, the conclusion seems to be but fair, that as Ceylon imports to this market increase, we shall find those of China quite relatively diminishing until competition by that country is quite broken down. Altogether, we think here that there is a consensus of evidence to induce the belief that, while Ceylon planters can yet for some time to come stem the tide against present low prices without danger to their enterprise, neither China nor India occupy the same favourable position. China tea is already being diverted into quite unaccustomed channels of trade in which as yet Ceylon does not need to enter into competition, while in India the large Companies find themselves compelled to refrain from breaking much of new ground, being satisfied if they can only just hold their own with the area they have under cultivation through the present era of low prices. Some such course as is being adopted in India would appear to us to be judicious to counsel as regards Ceylon, but you will observe that

Mr. Roberts lays stress upon the advantage to the producer in Ceylon of the home trade having large supplies to handle, and I but recently gave you his reasons for that opinion. Many of us here feel confident from a review of all the circumstances that, so long as you can just make a profit out of existing rates, Ceylon should not wholly follow the example set by India as to restriction of cultivation; though, doubtless, it will be wise to exercise caution and only to plant on such land, and under such conditions, as are certain to enable you to produce fine qualities of tea.

CINNAMON CHIPS IN CEYLON.

MEETING OF ESTATE PROPRIETORS AND MANAGERS.

A meeting was held in the hall of the National Association this afternoon to consider the means to adopt for decreasing the output of cinnamon chips and for suppressing the manufacture of cinnamon leaf-oil. There were present:—Messrs. Wm. Jardine, M. D. Cockburn, R. A. Miranda, Manuel de Mel, Jacob de Mel, Fred. Schradler, J. F. Drieberg, S. R. de Fonseka, W. D. Abrew, D. D. H. Perera, F. Drieberg and A. W. Beven.

Mr. JARDINE was elected to the chair. He expressed his regret at not seeing more proprietors of cinnamon estates present, but said he had had letters from other gentlemen who were quite willing to give their support to the resolutions that would be brought forward. They were perfectly cognizant of everything that had taken place hitherto with the view of trying to suppress the preparation and exportation of cinnamon chips. Previous to 1868-69 he believed that no chips were exported from Ceylon. In that year 1,427,490 lb. were exported. Now with the large increase of the acreage of cinnamon the total export was from 500,000 to 600,000 lb. of chips. Where they got twenty years ago the chips to send forward this enormous quantity of almost three times the present export was a problem. He observed also that in that year the export of quill bark rose some 200,000 lb. above that of any previous years. It was simply impossible that all that could have been cinnamon chips: there must have been a lot of other chips sent away to make up that enormous quantity. (Mr. Cockburn:—"Chips of the old block.") For the next few years the export of chips fell, and seldom exceeded 260,000 lb. But in 1879-80 there was an increase to 474,484 lb, and from 1883-84 to the present year the quantity exported annually was fluctuating between 500,000 lb. and 600,000 lb. From 1879-80 there was a steady increase in the export of quill bark which rose from 1,219,308 lb. in 1878-79, to 1,793,893 lb. in 1886-87, and the present amount exported might be taken at something close upon 1,700,000 lb. annually. With those large quantities thrown upon the market annually, prices which in 1881-82 ranged from 7d to 2s 7d per lb. fell steadily year by year till at present they ranged from 6d to 1s 5d, and he did not think he was far wrong in saying that the average price for the generality of cinnamon was not more than 9d per lb. all round. With such low prices was it to be wondered at that proprietors were anxious to cast about for some means of remedying the present state of things? Growers were agreed in thinking that the large export of chips was to blame for the present low prices, but without some understanding and combination amongst themselves there was no chance of effecting any improvement. He was, however, hopeful that that meeting would help towards that end. He had promise of support from a large number of large and influential owners, who although not

present that day would gladly join in the movement, for their letters to him stated as much. A few had demurred to certain parts of the resolutions that would be proposed, but he hoped something definite would be arrived at. There was another subject connected with the price of cinnamon, and that was the manufacture of cinnamon leaf oil. He thought that all owners of estates should refuse to permit the manufacture of cinnamon-leaf oil upon their estates. The small sum that was paid for the privilege of using the leaf was simply not worth taking into consideration, whereas the loss to the estate from the leaves and from throwing on to the market oil which competed with their cinnamon bark should be, if possible, suppressed. It had been said in some quarters that by withdrawing cinnamon chips they would leave room for the introduction of cassia to take its place. He did not think they had any need to fear on that head. If cassia ever was to oust cinnamon it would have done so long ago, for he believed the annual export from China was something over 13,000,000 lb., whereas the export of cinnamon of all kinds from Ceylon was barely over 2,000,000 lb. Having stated the objects of the meeting he next read letters he had received on the subject from Mr. Beven, Mr. R. Piachaud (Jaella), Mr. H. P. Fernando and Mr. John Abevasinghe, all approving the proposed resolutions. There were also one or two letters from gentlemen who dissented. They said they were quite willing to join in any movement for the suppression of the exportation of chips, but they could not agree to discontinuing the preparation of chips entirely as they have stills for manufacturing cinnamon oil, but they would undertake only to prepare chips for that purpose and not for sale or for exportation. That was a question for the meeting to discuss and give an opinion upon.

Mr. S. R. DE FONSEKA proposed:—

That this meeting of gentlemen interested in cinnamon deems it desirable to give up the preparation, sale and export of cinnamon chips, which it is believed helps materially to keep down the price of quill cinnamon.

He said this subject had engaged his attention for the last three or four years, and in the early stage of the Agricultural Association they thought it desirable to bring the matter forward, but owing to circumstances over which they had no control they could not then successfully bring about the end that was desired. He did not think it was necessary for him to enlarge upon the resolution. The advantages that estate proprietors would receive from cinnamon chips not being exported to England, and not being manufactured in Ceylon, would be patent to all. Their agents in England, as well as others who had studied the subject, had all along stated that in consequence of the exportation of cinnamon chips to such a large extent quill cinnamon had gone down in the market. That being so he thought all cinnamon estate proprietors ought to be thankful to Mr. Jardine for the interest he had taken in the subject, and for the trouble to which he had been put in convening that meeting. Though there was not a very large attendance he thought the interests of most of the cinnamon estates were represented, and he was personally aware of the cordial support which would be given to the movement by many who were unable to attend the meeting. (Applause.)

Mr. M. DE MELL seconded the motion.

Mr. COCKBURN, before the resolution was put to the meeting, pointed out that the question which had to be answered was this:—If they

stopped the preparation and the shipment of chips, would cinnamon be used in the place of chips in England: in other words would cinnamon be used for the same purposes for which chips were now used. He thought if they settled that question they could agree to any resolution and sign any paper. He himself, with his long experience, was inclined to think that any amount of resolutions would not stop the scraping of chips by the small landed proprietors. [The Chairman: We do not expect that.] He believed the chairman mentioned the quantity of chips exported annually from Ceylon as from 500,000 lb. to 600,000 lb. Some large proprietors also scraped, and if they took a proportion of that quantity and placed it towards those large proprietors, he thought the balance would be found larger on the part of the small proprietors. If the large proprietors combined not to scrape chips they had still to deal with the small proprietors. He thought the step that was now being taken a good one, and if they did all in their power to prevent the preparation of chips themselves, the small proprietors would probably find that it would not pay them, and would cease from scraping. He begged to support the resolution.

The CHAIRMAN said the question raised by the last speaker was one that he was not in a position to answer. He could not say for certain that the suppression of perhaps one half of chips, which was what they hoped to effect, would cause even the lower grades of cinnamons to be used for purposes for which chips were formerly used, but he was inclined to think that if cinnamon chips had been used for certain purposes for a number of years and they were withdrawn from the market, there was nothing else to take their place, and that inferior qualities of quill bark would be used for those purposes. He thought that was a reasonable surmise, but it was a question, of course, that would have to be tested by time. They did not expect to get the consent of all the small proprietors, as they knew that was impossible, but they hoped to get a sufficient number to represent one-half of the chips now exported, and if they did that he thought they would have achieved something.—The motion was then put to the meeting and carried unanimously.

Mr. SCHRADER proposed the second resolution. He regretted to find so few proprietors present as this was a matter concerning them all, more particularly those who were largely interested in it. They left the small proprietors alone, because he thought the large proprietors might endeavour to influence them hereafter, but for the present it was necessary they should all combine to make one strong effort to put down the shipping of cinnamon chips which, to a very great degree, had brought down the price of good quill bark. If chips were not shipped to England they might be positive that the inferior quality of quill cinnamon would take its place, and whatever loss there might be in withholding cinnamon chips it would be more than recouped by the higher prices for quill bark which would be obtained in England. (Hear, hear.) The resolution was as follows:—

That in order to give effect to the foregoing resolution a committee of the following gentlemen be appointed to draw up and circulate amongst owners of cinnamon properties, a letter for signature of proprietors and representatives of proprietors binding themselves on their honor to stop all scraping of chips from their cinnamon for a period of 2 years from 1st October 1889 and to adopt such other measures as may seem to them necessary to secure the end in view.

They might limit the effort to two years, and

if they found there was no improvement they might revert to the old system. The effort, however, could only be made with unanimity, and he trusted they would find that. (Hear, hear.)

Mr. MIRANDO seconded the resolution, remarking that though there were few cinnamon proprietors present he believed they would mostly give their support to the object aimed at, and the proposed letter would bring them nearly all to combine.—The following gentlemen were then proposed to form the Committee:—Messrs. S. R. De Fonseka, C. H. De Soysa, Jacob De Mel, R. A. Miranda, J. F. Driberg, W. Jardine, G. De Croos and Jeronis Peris.

The resolution being put was carried unanimously.

Mr. JACOB DE MEL proposed "That all who sign the letter referred to above should also agree not to permit the manufacture of cinnamon leaf oil upon their properties, or allow the removal of leaves for that purpose."

Mr. COCKBURN seconded the resolution, and pointed out that good cinnamon oil in 1877 fetched 4s 8d per oz.; the same quality of oil in 1886 fetched only 1s 8d per oz. Many of the stills in consequence, he believed, had stopped manufacturing cinnamon oil. If it did not pay to manufacture pure oil he could not for the life of him make out how cinnamon-leaf oil would pay.

The CHAIRMAN said those were all the resolutions that had suggested themselves as being necessary, but he had come prepared with a draft of a letter to be signed by all present at that meeting who were agreeable to give up the preparation of cinnamon chips and to sign their names to a document to that effect, but he thought it was better that they should not do so until they had had a meeting of the Committee to decide upon the tenor of the letter. He was very glad indeed that they had achieved so much. Things seemed to him more hopeful, and he trusted that by the efforts of the Committee they would be enabled to carry the matter to a successful issue.

The meeting concluded with a vote of thanks to the Chairman, proposed by Mr. De Fonseka and seconded by Mr. Schrader.

A Committee meeting was afterwards held.

SWARM OF BEES IN CEYLON.

(To the Editor of "The Field.")

SIR,—During our stay at Colombo, Ceylon, the other day, a curious case of bees swarming occurred, which I venture to send an account of to you, if you consider the case uncommon.

On Saturday, April 27th, at about 8 a.m., an enormous mass of bees swarmed under our foretop, almost covering the fore-end of the trestletrees, viz. a space of 2 ft. 3 in. long and 2 ft. 4 in. deep (this was the extreme depth of the swarm.) They continued to swarm, and remained for the space of two and a half hours, when they suddenly flew away in a small cloud to the island, clear of the houses, &c., a distance of one and a half miles. Such a strange sight has never been seen by any officer of our ship before. I may mention that the "little monsoon" had broken, but that day it was hot and fine. The usual noise, and more, was going on, as steamers were close to us, passing in and out of harbor.

GEORGE M. LECKIE, Senior, Lieut., R.N.

H. M. S. "Sapphire," Suez, May 31st.

THE DECADENCE OF CINNAMON.

In the time of the Dutch monopoly the famous cinnamon of Ceylon, the finest by far produced in the world, and the export of which was restricted

to the limit of the ascertained demand, occasionally realized for firstclass bark a price approaching £1 in money for one pound of bark, and even so lately as 1830, in the British period, the average price of Ceylon cinnamon in the London market was so high as 8s per lb. Thence the descent was rapid, under the influence of the abolition of the monopoly and the enormous increase of exports resulting from free trade in the article, down to 1s 3d in 1888, at which rate it was deemed that the cost of production and careful cultivation was scarcely covered. The average export from Ceylon in the monopoly days rarely exceeded half a million of pounds. With the absence of all restriction the exports rose rapidly until in one year, what with "chips" (previously worked up in the distillation of cinnamon oil) added to the baled spice, the figures closely approached three millions. The large proportion of chips included in the exports at last reduced the cinnamon of Ceylon to the level of a competitor with the Chinese bark, known in the market as *cassia lignea*. Combination was, a few years ago, resorted to, in order to abolish or restrict the export of chips, but the attempt broke down; and now it remains to be seen what success will attend the recent effort, the nature of which is reported in the *Observer* of Saturday. Our fear of another fiasco is founded on the very circumstance which, curiously enough, led Mr. Cockburn to hope, although with a good deal of hesitation, for good results. This gentleman is reported as saying:—

He thought the step that was now being taken a good one, and if they did all in their power to prevent the preparation of chips themselves the small proprietors would probably find that it would not pay them, and would cease from scraping. The logical conclusion would certainly be the reverse of this, namely, that the small growers who have not joined the compact against exporting chips will rather find the export so profitable, when the competition of the larger producers is removed, that they will not only persevere but gradually have their example followed. The analogy between tea and cinnamon is, in some respects, curious and striking. Mr. Jardine as chairman of Saturday's meeting announced that the average price of cinnamon was down to 9d, as nearly as possible the figure to which, under rapidly increased production and export, Ceylon tea has fallen. Then, while it has been necessary to warn Ceylon tea planters, that, if they cease exporting low quality and therefore cheap teas, the Chinese will rush in where they feared to tread; so at Saturday's meeting the question was very naturally raised whether the withdrawal of Ceylon cinnamon chips from the market might not result in merely leaving room for so much more "cassia" bark from China and other sources. The analogy between tea and cinnamon is however of very limited extent, for while the former is now a necessary and favourite article of food with a large portion of the human race, and the consumption is likely to increase indefinitely, cinnamon and the oil distilled from it are almost wholly luxuries, the limit of the use of which seems to have been reached. Cinnamon bark is used to flavour chocolate and puddings, as an ingredient in the "incense" of Romanist churches, and a constituent of Thorley's food for horses. In medicine and confectionery the bark and oil are used to some extent, while cinnamon and sulphur are combined in a new mode of preserving food (birds and other creatures being preserved whole) which recently created excitement in Britain and Australia. Except in this latter direction we do not see much prospect of increased consumption of our once famous and costly spice. One of the most striking proofs of the fall in value of cinnamon

as a cultivated product is to be found in the fact that the shrubs are being rooted and cleared out in favour of coconuts over a large portion of Mr. De Soysa's plantation connected with Alfred House, which we have been in the habit of showing to strangers as the perfection of cinnamon cultivation. We suspect this process of extermination is now largely pursued, instead of that of extension, so common some years ago.— It will be observed that a pledge was resolved on at the meeting against the manufacture of cinnamon-leaf oil. The prohibition, as we understand it, is in the interest of the fine aromatic oil distilled from cinnamon bark, generally put to this use in the shape of chips. The two essential oils are so different in quality and taste,—that drawn from the leaves closely resembling clove oil and being employed to rub inside the covers of books as a preservative against fungi and insects,—that we can scarcely conceive of a successful attempt to adulterate the very much finer oil with the coarser, the latter being entirely destitute of the peculiar and delicate flavour of cinnamon. If, however, it is true that the delicate citronella and lemongrass oils of Ceylon are adulterated extensively with kerosene, we are prepared to believe in almost any attempt at mixing an inferior substance with a superior. The coarse and pungent odour of the specially brittle leaves of the cinnamon tree as contrasted with the delicate aroma of the inner bark, or the oil distilled from it, is really one of the curious peculiarities of this famous and once valuable plant, the other being that from the roots a substance resembling camphor is prepared which the Sinhalese manufacture into candles for festive occasions. On the other hand the so-called "cassia" plants of China (a variety of cinnamon); while their bark is inferior to that obtained from the Ceylon plants, grow leaves with a much more pleasant scent than that which characterizes the leaves of the Ceylon bushes. So Dr. Trimen reported on receiving plants from China. Dr. Trimen added, that probably China supplied the cinnamon of the Mosaic and other ancient writings. This does not seem to us so certain, although attempts have been made to derive the very name from the land of Sennim. Old writings are vague as to the origin of products collected by trading fleets, and if, as many now believe, China received the tea plant from India (Assam), it may be that the celestials, who had early and large intercourse with our island, got their cinnamon bark and ultimately their cinnamon plants from Ceylon. What is certain is that the product which was once so valuable in commerce and for which Ceylon was so famous for many ages has fallen on evil days and now resembles silver in the days of Solomon in being little accounted of. Ceylon has swamped the markets of the world with cinchona and cinnamon, and strenuous efforts to open up new markets must not be intermitted lest the same fate should befall tea. The difference of course remains that tea is not merely a medicine or a luxury, but a valuable article of food, the use of which is certain to increase with the advance of population and wealth in the world.

GEMMING IN SABARAGAMUWA.

No. II.

Sabaragamuwa, 19th July.

Some new gemming lands have been discovered in the neighbourhood of Balangoda on the left bank of the Wallawe-ganga, some 8 or 10 miles down, and some, good finds have been made. One

sapphire was valued at R2,500, and several small ones found in the same pits were sold for over R500. The gems are of the first water—very pure and of a beautiful rich dark blue, regular Rakwana colours.

RUSH OF NATIVE PROSPECTORS.

In consequence of the above discovery a regular stampede of native prospectors have flooded the town and surrounding of Balangoda, but much to their sad disgust and disappointment, for the Ratemahatmaya has made several arrests for gemming on Crown land, and a few out of the many were fined heavily, so that those who cannot afford to use a little "soft soap" and to be allowed to go on with their work are loafing about the place with hanging heads and long faces.

GEMMING LICENSES REFUSED.

It appears some of the land where this rich stratum of gravel exists contains valuable timber and the Government Agent has refused to grant licenses to gem for fear of undermining the trees; there is also the inability to look after illicit gemming, which goes hand and hand with licenses, and would require an army of soldiers to look after them and protect the rights of Government.

DIFFICULTIES IN THE WAY.

There is plenty of land adjoining the Government land belonging to natives, but they are afraid to allow pits to be opened, as they hold very indifferent titles—in fact no title at all except that of inheritance. The river gemming has been stopped also, and licenses, I am told, refused, so those restless and adventurous spirits must "stampede" to some unexplored regions or back to their rich Government forest—Handapan Ela in Rakwana—where

SOME SPLENDID CATSEYES

have been found by simply turning over the surface soil. I heard of one a few days ago having changed hands for R5,000. I saw the catseye in the rough, it was in size and shape like a door handle with a splendid shifting ray right in the middle. It would be interesting to learn what becomes of this gem, but I suppose it would be impossible to follow it perhaps through many native dealers' hands before it finds its way to the wearer of it as an ornament of jewellery.

SABARAGAMUWA AND CALIFORNIA.

The position of Sabaragamuwa with regard to gemming is something like that of California—some forty years ago full of prospectors who went about from place to place sinking a pit here and there, taking and washing the gravel that was found between its four walls, but nothing more, and wherever a lucky find has been made there is a rush, and so on those old time prospectors go till a good find is made, when off he goes back to the lowcountry sea border. How long is this sort of gambling to go on before some company is started with capital and European enterprise to carry on gemming in a systematic manner?

SUGAR.

According to the *Kölnische Zeitung*, delegates from England, Germany, France, Belgium, and Russia are to meet in Brussels at the end of June with a view to the establishment, by an English syndicate, of a sugar bank with a large capital. The bank is not to trade on its own account, but will occupy itself exclusively with the affairs of its customers. The headquarters will be in London, and branches will be set up in the countries named. "Sugar having become of late years more and more an exchange article," adds the German paper, "the relations of the international sugar market have become extraordinary and peculiar,

and persons in the commercial and industrial circles of those countries where sugar is produced or consumed are beginning to cast about for a remedy to the existing state of things."

The report of the directors of the London Produce Clearing House, Limited, to be presented at the forthcoming general meeting of the shareholders, states that the accounts show a net profit of £5742 4s 8d., which it is proposed to carry forward to profit and loss new account. The preliminary expenses of the company have been borne by the founders. The business of the Clearing House during the past year was limited to coffee and sugar, and was, to a large extent, initiatory, which is shown by the fact that of the transactions in coffee (2,265,550 bags) more than half (1,263,500), and of those in sugar (1,277,000 bags) over two-thirds (873,500) were registered during the last four months. The advantage of the Clearing House to trade in giving facility of sale with security of contract, and thereby attracting business to London, is every day becoming more recognised, and, as a consequence, tea has just been included in its operations, while negotiations are in progress for the admission of other leading imports. In accordance with the articles of association, the following directors retire from office—viz.: Hermann Fortlage, Esq., Francis John Johnston, Esq., Henry John Jourdain, Esq., who, being eligible, offer themselves for re-election.—*H. & C. Mail*, June 28th.

PLANTING IN NETHERLANDS INDIA.

The Government in Java has taken steps to encourage the cultivation of trees and shrubs yielding valuable perfumes. Both headmen and people have been notified that the authorities expect them to make a move in that direction.

The *Locomotief* says that the coffee enterprise is looking up on the west coast of Sumatra. New estates are being opened out.* There is plenty of land fit for cultivation, but, unhappily, the scarcity of labour hampers progress in this respect.

In East Java heavy rains have materially checked sugar-cane crushing, but planters look hopefully upon the future, from the rise in the price of that article. Coffee growers, though at a disadvantage owing not only to the wet weather, but also to leaf disease, express satisfaction in consequence of the high prices ruling for their product.—*Straits Times*, 10th July.

MR. C. DRIEBERG ON THE GEOLOGY OF CEYLON.

As a fair specimen of the information supplied in the first number of the *Magazine of the School of Agriculture*, on sciences allied to that of Agriculture, we copy the first of a series of articles which the Editor, Mr. C. Driberg, promises, on "some of the geological formations of Ceylon." Very fittingly he commences with our all-prevalent primary rock, gneiss, one of the most protean of the metamorphic series. Happily for the fertility of the resulting soil, most of our Ceylon gneiss has, as one of its main constituents, a form of felspar (orthoclase) rich in potash, which is readily dissolved under the influence of our hot and moist climate and its own self-contained stores of water. Mr. Driberg describes the rock as foliated, a term closely equivalent to stratified. We are old enough to remember the time when gneiss was regarded simply as the constituents of decomposed granite diffused through water and settling in that element into layers, just as we see them in normal gneiss and even where the rock has been upheaved into the perpen-

* The exact truth in this matter is of importance, because if new coffee estates are being opened up, leaf-disease must have abated in virulence,—contrary to experience in Ceylon.—Ed. L. R.

dicular instead of the horizontal. But this theory of long-continued settlement in quiet water has long been abandoned for that of metamorphic changes under the influence of heat, pressure and magnetic attraction. There may not, indeed, be anything wild in the idea, entertained by a writer on the gems of Ratnapura, that electricity operates largely on rocks and minerals, in the shape of the lightning flashes which our atmosphere sends into the earth. Few persons have any idea of the large amount of "interstitial water" contained in the hardest granitic rocks and of the influence of such moisture in inducing decomposition and metamorphic action. As Mr. Drieberg has mentioned "eruptive" forces, we may hope that he will help us to a decision of the controversy regarding traces of such action in Ceylon, in any period short of the archæan. We have frequently heard and read of alleged evidences of volcanic action in Ceylon, but we have never seen any more closely connected with our rock formations than the pumice which has continued to be washed on our shores, ever since a year after the eruption of Krakatao.

Then, as to graphitic gneiss, in which plumbago takes the place of mica, sometimes so closely resembling laminae of the latter mineral that the natives believe in a transformation which is impossible, Mr. Drieberg will doubtless explain the happy peculiarity in our graphite-bearing formations, which has given Ceylon almost a monopoly of the refractory substance so valuable for crucibles in which to melt the precious metals and steel. In the rocks of North America there is abundance of graphite, but in a diffused condition, particles mixed in the rock, which are difficult and expensive to separate. What are the conditions and laws under which in Ceylon large masses of pure carbon are aggregated in sometimes extensive veins? and is the mineral, one of the oldest formations in our globe, still in course of growth and aggregation?

NOTES ON SOME OF THE GEOLOGICAL FORMATIONS IN CEYLON.

GNEISS.

By C. DRIEBERG, B. A., F. H. A. S.

GNEISS, one of the commonest formations in the Island, is a foliated crystalline-granular rock, consisting of quartz, felspar, and mica. The quartz is white or grey; the felspar is of the variety known as orthoclase (apotash felspar); and the orthoclase is often associated with plagioclase felspar, though it is no easy matter to distinguish between the two. When hornblende replaces the mica we get Hornblende-gneiss; Protogine-gneiss has talc instead of mica, and specimens of this variety were shewn me, got out of a quarry in Mutwal; Graphite-gneiss has graphite or plumbago instead of mica. It is simply its foliated structure which distinguishes gneiss from granite. In granite the crystalline particles are intimately mixed, while in gneiss, the quartz, felspar, and mica form folia, often running into lenticular layers of considerable thickness.

The question of the origin of gneiss is one that has not altogether been set at rest. The most generally accepted theory is that all schists are merely metamorphosed aqueous or igneous rocks—metamorphism being induced by great heat. In local or contact metamorphism the inducing cause is generally an eruptive mass, which, intruding in a molten or semi-molten state, alters, by its highly heated condition, the surrounding rocks. Where the metamorphism is regional, the heat produced is to be attributed to internal earth movements, which exert a powerful shearing and grinding action. It is probable that water plays an important part in most metamorphic changes. The interstitial water in rocks would convey the heat, derived from an eruptive mass or produced

by earth-movements, in all directions, and the chemical action of this water would favour the re-arrangement of rock-constituents.

The metamorphism by mere contact is well seen where an eruptive rock mass lies exposed, resting on clay or limestone producing in the former case jasperous stone, and calcareous silicates such as garnets in the latter. The gradual merging of the original rock—for instance clay—into the metamorphosed rock is most strikingly shown in places in the Matale district, where extreme instances of schistosity—resulting in seared and puckered foliated rock of very grotesque (often vari-coloured) appearance may be observed.

There exist, however, enormous areas of schistose rocks which exhibit no appearance of the gradations characteristic of metamorphism by the agencies I have indicated above.

These rocks, always the oldest in the region they occur, are the archæan schists, the junction between which and the over-lying strata being invariably an unconformability. Some geologists believe that these were chemical precipitates of the primeval ocean, laid down at a time when the temperature of the water was much higher, and the proportion of mineral substances much greater than at present—the result being what may be termed the chemical sediment of a thermal ocean. The weight of evidence, however, so far as it goes, seems at present to be against this view.—*Magazine of the School of Agriculture.*

THE EUCALYPTUS.—When doctors differ, who is to decide? Mr. Robertson recommends the extensive planting of the Eucalyptus (blue gum) on the Nilgiris, as a profitable investment. The Acting Conservator of Forests, in his last report, remarks that the tree, as a forest produce, is a failure.—*Madras Times*, 19th July.

DRY wood gives a hotter fire, and is more economical to burn than green wood, because the latter contains more water, and a large part of the heat of the fire is wasted in converting it into steam, which passes off up the chimney, thus carrying the heat into the outer air, where it is wasted.—*American Cultivator.*

A NEW TOBACCO Co.—The prospectus is published of "Lankat Maatschappij" (Limited), Sumatra, with a full capital of £125,000 in £1 shares. The present issue is 150,000 shares, of which the vendor takes 60,000 in part payment of the purchase money, and the balance (£15,000) in cash, these payments to include all expenses of promotion, &c. The company is already a going concern, and calculating the present crop at 2s 3d per lb. it is estimated there will be a profit sufficient to pay a dividend of 20 per cent. Next season it is proposed to plant on a large scale, when an enhanced dividend may be expected. It is very probable that the present crop may, however, prove more valuable than the estimate of 2s 3d per lb., as from the land of the Shanghai Sumatra Tobacco Company, which adjoins the estates of the present company, tobacco, which contained as much as 51 per cent of broken leaf, realised 2s 9d per half kilo. The most important fact we may direct attention to, however, is that the Deli Maatschappij, whose magnificent properties and dividends have been the admiration of so many, have consented to act as the representatives of the Company in Sumatra and Amsterdam, a fact which will ensure the produce being efficiently handled. Mr. Wortman, who is interested as one of the vendors, and who has had some fifteen years' actual experience of tobacco planting in Sumatra, is, we observe, one of the directors. It would be superfluous to say much to our readers as to whether tobacco planting in Sumatra is a success. The only elements needful are that the land should be properly selected, and that the seasons be favourable. That the first has been done we can be assured, as Messrs. Blumenthal and Schoeller, managers of the Deli Maatschappij, have reported well on the land; the second, of course, cannot be pronounced on.—*London and China Express.*

TEA ANALYSES AND COMPARISONS.

The literature of tea is becoming very extensive and in no country where this cosmopolitan plant is grown have greater and more important additions been made to the information respecting the natural history of the plant, its culture, its composition and manufacture, than in Ceylon. In the letter and tables which we publish today, Mr. Cochran has added to the services previously rendered by him, not only in the shape of analyses by himself, but by the quotation of results obtained elsewhere and discriminating remarks on the comparisons thus rendered possible. Our correspondent "Peppercorn," in commenting as he has a special right to do on her, Cochran's paper, dwells on one conspicuous conclusion to be derived from the comparative figures, viz. the superiority of Ceylon tea (of which the Rose-neath produce is a fair if juvenile specimen) in cleanliness or purity: the absence of foreign substances from the manufactured leaf. From 5 to 6 per cent is the normal proportion of ash in good tea gathered from well-grown bushes, and when the teas sent to the Melbourne Exhibition of 1880-81 gave ash results below 5 per cent, the explanation was to be found in the youth of the trees from which the leaf was gathered and the absolutely unsophisticated condition of the leaf itself. In total extract, on the other hand, our teas gave results hitherto unprecedented: in one case close up to 50 per cent of the weight of leaf. In the case of the spurious teas examined in the United States by Dr. Battershall, it will be observed that the ash after combustion was so great in quantity as from 7.95 up to 12.58 per cent, and that the proportions of ash insoluble in water and even in acid and of insoluble leaf were abnormally great. While 5 to 6 per cent is the normal proportion of ash in good tea, the superiority of quality in the leaf is largely dependent on the proportion of the leaf which is easily soluble. The insoluble matter need not be all sand, as we suppose some of the ash of leaf stalks must be more or less refractory, but the test of solubility remains true: the more soluble the ash, the purer the tea. Judged by this test, we find that the Indian teas examined in America gave the fair average of 5.613 of ash, but of this ash 2.092 was insoluble in water and .177 insoluble in acid. The average of insoluble leaf was 51.910, or over, one-half. The proportion of ash in the Ceylon teas, analysed by Mr. Cochran ranged from 4.97 to 5.30, the average being only a little over 5 per cent, against 5.613 for the Indian teas. But the proportion of ash insoluble in water and acid was much lower than in the case of the Indian teas the very highest proportion being only 1.91 per cent thus:

Insoluble in water 1.82
Do, in acid .09

In the case of the good China and Japan teas, the figures for total ash present nothing remarkable, except in the case of Japan dust, one sample of which shows 9.74 ash of which only 1.48 was soluble in water. There was dust other than tea-dust in this specimen. The finest and highest priced tea, "Formosa Oolong, choice, 1st crop, shows 6.50 per cent of ash, of which only 3.60 was soluble in water,—2.90 being insoluble in water and 0.86 insoluble in acids. Of the ash of medium congou, 6.36, only 3.00, or considerably less than half, was soluble in water. In respect of purity the Ceylon teas take first rank, by far. In regard to total extract, the Indian teas run from 37.8 to 40.350 per cent, while the Ceylon teas, although grown on old coffee soil, show figures from 38.40 to 43.02. In this respect also, the Ceylon teas are superior to the Indian, while the China and Japan teas shew 43.20 only in one case, the general run being much below this, down to 26.20 in regard to common congou.—A due proportion of tannin is absolutely necessary to constitute good tea, although it is a mistake to infuse the leaf so as to produce an extract mainly of tannin. The proportions of tannin in the Ceylon teas is certainly not excessive, 9.80 per cent to 12.36; against 13.040 to 18.368 for Indian and 12.26 to 19.96 in China. This latter large proportion was obtained from "first young Hyson, plain draw." Seeing how much talk there is about the mild flavour of China teas, the proportion of tannin, we confess, takes us by surprise. The Rose-neath teas are only five years old, and as they increase in age, so, we feel confident will the proportion of tannin.—We now come to the constituent on which the delicate and acceptable flavour of tea is supposed specially to depend,—theine. The comparison in regard to this component of the various teas runs thus:

Ceylon 1.64 to 2.18 per cent.
Indian 1.880 to 3.240 "
China and Japan .. 1.08 to 3.46 "

In this case the Ceylon tea compares unfavourably with India, and in the case of the finest teas with China and Japan, and yet Ceylon tea is credited with fine flavour and absence of pungency. We might again refer to the youth of the Ceylon tea and the comparatively low altitude at which it is grown. But the whole question of the circumstances under which theine is formed and its influence on the quality and value of tea requires further investigation. We are inclined to attribute a good deal of importance to that subtle oil of which Mr. Cochran speaks.—If the Ceylon tea we have been comparing with the products of India and China and Japan had been grown in virgin soil and had been plucked from bushes ten instead of five years old, the conclusions might have been still more strongly in favour of our insular leaf. Ceylon tea is a good tea and eminently pure, but why do we so frequently hear of its liability to "go off"? It must be due to climate or preparation, and whatever the cause the matter seems to demand the earnest consideration and prompt action of our planters so that the proper remedy may be applied.

UPCOUNTRY PLANTING REPORT.

AMERICAN AND CEYLON ANALYSES OF TEA: MEDIUM AND FINE PLUCKING COMPARED—MR. COCHRAN'S PAPER.

23rd July 1889.

Now that the American campaign for the pushing of the sale of our teas in that Continent is about to begin, the following able and interesting paper

which I am able to send you, on "American and Ceylon Analyses of Tea: 'Medium' and 'Fine' Plucking Compared," from the results worked out by our local chemist, M. Cochran, Esq., M. A., F. C. S., is highly interesting. The paper is complete in itself and wants but little from me to supplement it; still it may be useful to state that the tea which has been analysed is now exactly five years old, and that "fine" plucking means in this case a leaf and one bud; while "medium" was two leaves and one bud.

The completeness of Mr. Cochran's paper leaves little to be desired: still it is worthy of notice that the results of the American chemists in regard to the Indian teas are from samples representing 2,414 packages. It is clear that if we are to obtain a standard result, which we can place side by side with this Indian table, other estates will have to follow the beginning that has been made and a series of analyses be undertaken. If nothing else were established than "the cleanliness in the preparation of our commercial teas" as compared with either India or China, that alone would be worth the effort and expense. We all want to know, that what we swallow has been cleanly made, and if we can go to the American public and the world generally and say that here, in this important particular, Ceylon as usual tops the market, and that this purity has been established in the laboratory, it will add much to the chances of increased consumption. There is not a housewife in the land that would not prefer the clean article—other things being equal.

It would be hardly fitting perhaps that I should continue my letter to its usual length, considering the demand on your space which Mr. Cochran's paper calls for, and the other claims of the public. I am sure you will accept this as a legitimate excuse for my brevity. PEPPERCORN.

AMERICAN AND CEYLON ANALYSES OF TEA.

"MEDIUM" AND "FINE" PLUCKING COMPARED.

After considerable unavoidable delay, I have completed the chemical examination of the six samples of Roseneath tea, received on the 8th of May, with a view to determine to what extent the chemical composition of teas is affected by medium and fine plucking respectively.

As the planting community at present is interested in "pushing" its teas in America, I have treated these samples in the way chemical analysts do in America, at least in so far as their method is detailed in what may still be considered a new work (1887) on "Food Adulteration" by Dr. Jesse P. Battershall of New York. I shall preface my report on your samples of tea by giving you some of the results obtained by American chemists, borrowed from the work referred to. These analytical results will be interesting, as, although they may have been seen by individuals, they have not before been brought before the notice of the planting community generally.

In the following table of analyses made by Dr. J. F. Davis, under the supervision of Dr. Battershall, the latter observes:—"It will be noticed, if the same varieties of tea be compared, that, with some exceptions, their commercial value is directly proportional to the percentages of soluble ash, extract, tannin, and theine contained."*

* It was the writer who added these together and set them down in tabular form; but it is evident the expression "directly proportional to" may mean that they should be multiplied into each other or Dr. B. may simply mean that these constituents individually rise and fall in a general way with the price.—M. C.

The following are the results of analyses, by American chemists, of samples representing 2,414 packages of Indian tea:—

	per cent.	Average per cent.
Moisture ..	5.830 to 6.325	5.938
Extract ..	37.8 to 40.350	38.841
Total Ash ..	5.05 to 6.024	5.613
Ash soluble in water ..	3.122 to 4.280	3.516
Ash insoluble in water...	1.890 to 2.255	2.092
Ash insoluble in acid120 to .296	.177
Insoluble leaf ..	47.120 to 55.870	51.910
Tannin ..	13.040 to 18.868	15.323
Theine ..	1.880 to 3.240	2.736

Dr. Battershall also gives analyses of several kinds of spurious tea, received from the U. S. Consuls at Canton and Nagasaki (Japan). The analyses were made by himself:—

	1	2	3	4
Total Ash ..	8.62	8.9	7.95	12.58
Ash insoluble in water...	7.98	6.04	4.95	8.74
Ash soluble in water64	1.66	3.00	3.84
Ash insoluble in acid ...	3.92	3.18	1.88	6.60
Extract ..	7.73	14.00	12.76	22.10
Gum ..	10.67	7.30	11.00	11.40
Insoluble leaf ..	70.60	70.55	67.00	60.10
Tannin ..	3.13	8.01	14.50	15.64
Theine ..	.58	Nil	.16	.12

No. 1 partially exhausted and reired tea leaves, known as "chung suey" (clear water).

No. 2 is lie tea, made from wampan leaves.

No. 3 is a mixture of 10 per cent green tea,

and 90 per cent "lie tea." It is sometimes sold as "imperial" or "gunpowder" tea, and is stated to be extensively consumed in France and Spain.

No. 4 is "scented caper tea" consisting of tea-dust made up into little shot-like pellets by means of "congee paste" (*i.e.* boiled rice), and said to be "chiefly used in the English coal mining districts."

The tannin and theine in the samples of pure Indian tea quoted above are considerably higher than the same constituents in six samples of Roseneath tea, which I have just analysed. I estimated only the tannin and theine in the extract, which was obtained by boiling the tea (without any previous bruising or powdering) for an hour in a measured quantity of water, taking no account of what might be left in the insoluble leaf. I believe in the analyses by the American chemists also, only the tannin and theine in the extract are taken into account; but Dr. Battershall does not make this point quite clear. I am of opinion that there are Indian teas, in which the percentage of tannin and theine falls very much lower than the lowest of the Indian teas quoted by Dr. Battershall. Along with the analyses of the six samples of Roseneath tea, I give results obtained from a sample of Neilgherry tea which I analysed at the same time.

Present London value	Moisture	Total Ash	Ash insoluble in acid	Ash insoluble in water	Insoluble Leaf	Extract	Ash soluble in Water	Tannin	Theine
7½d	4.30	5.04	.09	1.82	57.40	38.40	3.92	1.64	53.05

No. 7	Tea from the Neilgherries.—Sample gone off. Judged by leaf			7½d about

NOTE.—It is impossible to be very accurate in the valuations of these samples, as they have gone off.

JAS. A. HENDERSON.

I was not surprised to hear that the Neilgherry sample had "gone off," as it had been several months in Ceylon. I got it from a friend, and do not know under what circumstances it was obtained; but it shows that the particular flavour and aroma, by which the tea taster judges of the value of teas, must be rather fugitive qualities; when even the Ceylon samples had "gone off" between the 8th May and 18th July. The samples were put into stoppered bottles immediately on receipt, and were only opened a few times, chiefly for the purpose of removing portions for analysis.

If the values were to be estimated according to their respective amounts of extract, soluble ash, tannin and theine added together, the three qualities of medium plucking would be in the proportions 53.06, 57.92, and 58.2; and the three qualities of fine plucking, in the proportions 59.45, 59.82, and 60.92. The average figures then would be, for medium plucking, 56.39; for fine plucking, 60.06; or, if we take the figures for the extract only, which really includes the tannin, theine and the soluble ash, the averages would be for medium plucking, 43.57; for fine plucking, 42.5. It would appear, therefore, that while there is a substantial difference in the commercial value in favour of fine plucking, there is a very trifling difference in the chemical composition of the two qualities.

The analyses of these Ceylon samples shows, in a marked degree, the cleanliness in the preparation of our commercial teas. The amount of ash insoluble in acid, which means sand, only averaged .09 per cent, or half that of the Indian samples. These latter again have less than a third of the amount of sand or insoluble ash in the Formosa, Congou, Young Hyson, Gunpowder and Japan teas.

It is to be regretted that, as yet, there is no very reliable process for estimating the volatile oil in tea; as this might furnish valuable data for valuation; but those determinations which have been published only show a range of from .6 to .87 per cent.

In conclusion, I should mention, that the Ceylon teas analysed were grown upon old coffee soil at medium elevation.

Teas grown upon new clearings might be expected to show higher percentages of theine, as this alkaloid contains a large proportion of nitrogen.

M. COCHRAN.

DIRECTORS:

Alex. William Crichton, Esq.; Andrew John MacDonald, Esq.; William Cotton Rohde, Esq.; Grant Healty Tod-Healty, Esq.

London Office—South Sea Chambers, 97 & 98, Bishopsgate Street Within, E. C.; Ceylon Office—Baillie Street, Colombo; Mauritius Office—Place d'Armes, Port Louis.

REPORT OF THE BOARD OF DIRECTORS:

The directors have much pleasure in submitting to the shareholders their report of proceedings during the third year of the working of the Company. The net profit as shewn in the audited accounts annexed herein amounts to £25,803 16s 11d (including £217 17s 5d brought forward) as against £25,841 0s 8d last year. An interim dividend of 3s 6d on the preferred shares and of 6d on the fully paid ordinary shares, and of a proportionate amount on the partly paid ordinary shares was paid in February last, and the directors now recommend the payment of a similar further dividend making a total payment of 7 per cent per annum on the issued preferred shares, and of 5 per cent per annum on the ordinary shares, in proportion to the capital paid up thereon for the year ended 31st March: 1889. The further dividend now recommended as above, will, if assented to by the Meeting, be payable on the 1st August, 1889, at the London Office of the Company's Bankers. In accordance with the statement at the Extraordinary Meeting of the Company held in February last, application was made to the Stock Exchange Committee for a quotation of the Company's Preferred and Ordinary Shares, which was granted in due course. In March last the Directors decided on issuing 4½ per cent. Debentures of the Company to the amount of £150,000. The issue was made to provide additional working capital to extend the business of the Company and for the other purposes mentioned in the Prospectus. The Directors are glad to report that these debentures have all been subscribed for and a saving in the working expenses of the Company will be effected by this additional Capital as the rate of interest payable will be less than that hitherto paid on the necessary advances required for upkeep of the Estates and the cultivation and gathering in of the produce. The expectations of the Directors with regard to tea have been realized, as a large additional crop was secured, but in view of the falling market they consider that the interests of the Company lie rather in the direction of increasing the yield per acre and improving the manufacture by judicious outlay and careful attention rather than in extending the cultivated area. With regard to coffee, the Directors have used their utmost endeavours to keep up this product which now commands such high prices, and they are happy to report that a marked decrease has been observed in its enemies, bug and leaf disease. As to Cinchona, although the price of bark has lately ruled very low, the Directors are led to believe that the large shipments which have for some time past come from Ceylon and depressed the market, cannot be maintained for a lengthened period, and they anticipate that the principal source of supply of this article being thus diminished, the price of bark may show a good recovery within a corresponding time. The crop of sugar from the Company's estates during the year was a good one, but the present rise in the price of sugar came too late to affect the Company's profits during the year under review. It is hoped, however, that, owing to the small stocks, a higher range of prices than usual as to sugar may be looked for during the coming season and that proportionate results may be attained. The Company's estates, both in Ceylon and Mauritius, are reported to be in excellent condition, and favourable

accounts have been received from the managers in both islands of the prospects of these properties in the coming year.

THE NEW POSITION OF COCONUT OILS.

The market for coconut oils has been entirely reversed recently by marine accidents which have prevented the arrival of expected supplies. The "Mohur" has been overdue some time and may not come to this port from Mauritius until September with her 250 tons of Cochin oil and 600 tons of Ceylon oil. The next vessel to meet with delay on account of leakage is the Italian bark "Fede e Speranza" with 325 tons of Ceylon oil, and it is uncertain when it will come to hand. The early news about the "Queen of Nations" was more than confirmed by the cable reports from London on Monday which stated that the vessel had been wrecked on the African coast and that little if any salvage was left. The last unfortunate event is very important to the trade if true, as the vessel contained within a fraction of 800 tons of Ceylon oil. Still another is added to the chapter of accidents by the bark "Star of China"

having to be placed on the dock for repairs, while ready to be loaded with oil at one of the Ceylon ports. The next vessels due with Ceylon oil are the "Marquis of Lorne" with 700 tons, "Countess of Aix" having 55 tons and the "Harvard" with 100 tons and 40 tons Cochin oil. A large portion of the stocks afloat has left first hands, and part is intended for direct consumption. The delay of these vessels would embarrass the trade, as the entire stock of Ceylon oil in dealers' hands on spot is closely estimated at 250 tons, the remainder in store being held for consumers. The amount of Cochin oil on spot is placed at 75 tons, and the only supplies afloat are the 40 tons on the "Harvard" which were sold last week in two lots at an advanced price. Additional stock is expected to arrive in September if no unforeseen circumstance happens to prevent.

The better statistical position of both articles caused renewed interest to be manifested in the market during the past few days, and some unusual transactions resulted aggregating 150 tons of Cochin oil on spot at six cents and a fraction above; also 40 tons afloat at six and a quarter cents, and 200 tons Ceylon oil in store at five and three-eighths to one-half cents. The improvement has every appearance of stability during the summer months at least. Cuban oil continues to have a small outlet at five and a quarter cents, but it is not considered an element in the market on account of limited available supplies.—*Oil, Paint and Drug Reporter*, June 12th.

STEAM BOILERS AND PLANTERS.

If planters would pay as much attention to the interior of their boilers as they do their own insides, they would save time, fuel, money and wear and tear of boiler plates. In order to assist them in doing so, Mr. Bertie Short has established an agency for the Most Perfect Boiler In-rustion Preventive that has ever been discovered, viz., The Downie Eucalyptus fluid. It is the *only* thing that will successfully remove all scale from steam boilers, prevent its formation, and at the same time preserve the iron entirely from pitting and corrosion. It is purely vegetable and will not cause foaming and priming, but will tend to prevent it in water containing alkalies. It will extend the duration of boilers 150 per cent, and effect a great saving in fuel, as scale is a non-conductor of heat. No matter to what extent old scale exists it undermines and loosens it, thus saving the necessity for all chipping and hammering inside boilers. Objection might be urged to its use in steam boiling indigo, but it does not impregnate the steam and is in fact used in washing bottles for aerated waters and beer. It is in general use in the American Navy and the Pacific Coast Steamship and numerous other companies. Thousands of testimonials testify to its efficacy, but perhaps the one which will have most weight with planters in these districts is the following from Mr. J. Crofts, when he was Chief-Engineer of the United States man-of-war "Newport." "A little over two years ago I began using the scale preventive and remover. The scale was slowly removed and for two years there has never been a scaling hammer in the boilers, and no repairing of any sort has been necessary. The boilers are entirely clean and free from scale and rust. The preparation has entirely prevented rusting and pitting." All orders for this invaluable specific should be sent at once to the hub of Bengal—Jainpore, Tirhoot. Bertie drank a pint of it himself and in one act it drove all the gout out of his system.—*Indian Planter's Gazette*, July 2nd.

HOW TO GROW COTTON SUCCESSFULLY; AND THE REQUIREMENTS OF THE NEW MILLS.

We are indebted to a Kelebokka planter for permission to republish information which he has received from one of the first authorities on cotton in Manchester. This firm writes as follows:—

"The introduction of Sea Island seed and the seed other superior growths into Egypt, the West

Indies, the ordinary cotton fields of America, Australia, and various other places has ended in much disappointment owing to the rapid deterioration in the quality of the cotton. The 1st year's growth is of good quality, small in quantity; the 2nd year's much worse, but more in quantity; the 3rd and succeeding years inferior, almost trash, so that planters have abandoned the attempt, except in Fiji where the cotton keeps of fine quality but small in quantity.

"The rapid falling-off in the quality of cotton is through the process of cross-fertilisation with the native cotton caused by bees and other insects.

"The only way to grow cotton successfully on places where the plant is indigenous is to take the seed from the best pods longest-stapled year after year until you get a greatly improved growth. This plan has been most successfully carried out in America notably by Mr. Peel and Mr. Allen, the best of whose growths are worth 1½d to 2d over the price of middling American. The same system has also been successfully carried out in Egypt by Mr. Ralli, who now gets quite fancy prices for his cotton. The cotton must be ginned in Ceylon, and I would recommend your sending out the hand gins made by Platts of Oldham, as they do not injure the seed which is worth about £7 per ton for crushing. Cotton sells better in Liverpool than London."

Our planting correspondent adds:—

"The defects in cotton to be avoided are:—broken fibre from bad ginning; loss of strength from damp; discoloration from dirt, sand, moisture, broken seeds, etc."

We are glad to learn that the Cotton Weaving and Spinning Company are getting out two of Platt's hand gins. As to the seed used for the new—or revival of an old—enterprise in Ceylon, we learn that the Company have now distributed from 6,000 to 7,000 lb. of the best kinds in different districts, equivalent—even at 2lb. an acre—to over 3,000 acres in cultivation of cotton! Not bad this for a beginning. Nevertheless, the Company are not going to depend on a local supply of cotton to begin with. The Secretaries, we understand, have arranged to get their supply from Tuticorin for the first few months—counting on full response in local crops from the beginning of 1890. It must be remembered that when once the Mills are started—as the energetic Manager hopes they may before many weeks pass away now—there must be no stoppage even for a day, if possible. We have heard the loss from a day's stoppage of the engines and machinery put at £100. Certainly, a sufficient supply of raw material as of firewood (now advertized for) and other requisites must be laid up in stock.

A correspondent the other day stated in our columns that "cotton seed" was hard to get and time was being lost in consequence; but on inquiry we learn that although so much has been distributed, the seed lately advertized by the Company's Secretaries is by no means exhausted, so that our correspondent can have as much as he requires on application.

TEA IN DARJEELING.

We are having almost continuous rain here with cold nights for the time of year. Not by any means the kind of weather suitable for tea. During the last few days sunshine even for a few minutes may be very well expressed by the algebraic sign, "and the natural result is that withering the leaf brought into the tea factories is a very slow process indeed, and the quality of the tea made is inferior as a general rule so far as strength in cup goes. So, I think, taken altogether, my forecast of the tea season has not been very far stray in any respect. The rainfall up to the 27th had been 39.15 inches, and dur-

ing the week to that date 10.81 inches. As I write—the morning of the 28th—the rain is coming down steadily, just as it had been doing all night and nearly the whole of yesterday. I have not the means by me of comparing this with last year, but I can make a pretty accurate guess from memory and can say that we have had a good deal more of Jupiter Pluvius's attention this than the corresponding period of last year. While on the subject of tea and prices, I may say I am glad to see Springside heading the list. The garden is a very old one and by no means large as regards area, but the results bear out the very true maxim that constant changes in management are a mistake. This garden has been under the same control during the last decade or more, and has always during that period given a very good return on the capital invested: By the way, I saw one of Davidson's new machines on a garden the other day. It had only just been set at work, but the manager expressed himself as being exceedingly pleased with the results so far. I, of course, and for very obvious reasons do not give the name of the garden; but I was told that several more of these machines are on their way to this district, and so I will be able to give your readers more accurate and more extended results later on than I am able to do at present.—*Cor., Indian Planters' Gazette, July 2nd.*

INCREASED ACTIVITY AMONGST DELI PLANTERS.

One of our Deli correspondents writes to inform us that some old Deli tobacco planters have lately acquired large tracts of land in the district of Bila with a view to form a company and to open a few estates before the end of the present year. "It would appear," says our correspondent, "that the land in Bila is, after all, not so inappropriate for tobacco planting on account of the backwater as was the general impression some time ago; on the contrary the shore formation in Bila is very different from that of other coast land in Deli, where the shores of the great rivers are rather high and the land deviates in the interior to a lower level than that of the river. In Bila, however, the shore lies rather low, but at a distance of a few yards the land rises gradually towards the interior. There are but few small rivers in Bila. The soil generally consists of a layer of dark coloured humus with a substratum of clay without touching upon sand, as is the case, at a very small depth, in the adjoining districts of Kwaloe and Assahan. The locality is easily reached by the great rivers, and communication between Bila and the outer world is all that can be desired. A Government steamer plies regularly every fourteen days from Bila to Deli and *vice versa*, whilst small steam launches carry on uninterrupted communication with the coast ports.

"That good tobacco can be produced in Bila has already been proved; and as regards the prices realized, former Bila planters had every reason to be satisfied, especially if it is borne in mind that being "coast" it had to undergo very close inspection and to support all the criticisms of the other planters who have an interest in its depreciation.

"The reason why an estate which was opened in Bila by a great Deli company had to be closed, is only known to a very few. The real facts are that the district of Bila being out of the ordinary circle of operations of the Deli company, the late planters forgot to take the most ordinary means of precaution to secure their crops from inundations, and planted almost to the water's edge of the Bila river, which will deluge at times; besides this they made the old mistake of opening too much land at the beginning and erected extensive buildings before they were certain of a good

result. Having, as already said, neglected to secure their crops against the periodical overflows of the Bila river, most of their tobacco was washed away, and they were eventually compelled to close their operations on an injunction from head-quarters. The deficit was large, but it was simply the consequence of waste and neglect.

"It is firmly believed that, advantaged by the experience their predecessors had to undergo, the men at the head of the present undertaking will be successful and prove that very good tobacco may be grown in Bila at remunerative prices."—*Straits Independent, July 6th.*

CONTRACTING CINCHONA BARK SUPPLIES.

The following opinion of an Uva planter, contained in a semi-private note, is worthy of being published in view of the recent decision:—

"I believe in no method that I have ever heard of being used to force a market up or down. Being, pretty deeply in as regards cinchona, bark nobody would more gladly welcome higher prices, but I think these should come about from natural causes, say a falling-off of supplies, or an increased consumption, and not from holding back supplies."

TEA CULTURE AND PREPARATION.

ANSWERS TO QUESTIONS.

II.

When is it best to prune, and how? I usually prune when my trees begin to show indications of stopping flushing and when much small banjy comes in with the plucked leaf. How one prunes must depend upon so many influences:—Altitude, jât of tea, quality of land, exposure, &c. As a rule at a higher altitude less frequently, good jât less frequently than inferior, good less frequently than poor land; exposed localities too cease flushing first. For 24 months I have seen tea bushes continue flushing under favourable circumstances, while in other spots tea has not run well for 12 months. Thus I know no general rule for pruning any more than for drinking or putting on more clothing.

The foregoing to make intelligible and of service would require about a column of print at least to put it into practical form, as indeed would almost each of "B."s 13 questions. Briefly however. The system must always change as frequently as the conditions. Undoubtedly most tea planters are now disposed to work their bushes lower than formerly, and I think 4 leaves are more usually left when tipping, instead of five or six inches of length of stalk. This catches the inferior, jât bushes which do not flush if left too long, as would be the case by measurement rather than by counting leaves.

Firing tea will always be a difficulty as long as China tea goes into the market. China teas are always brisk, consequently want good strong dull Indians and Ceylons to give them strength. As China shipments fall off, there will be a demand for flavour and briskness; consequently we shall hear less of overfired teas. There was a time when the London market preferred strong liquoring teas above all others; hard rolling, nay grinding into strength commanded the best prices; now flavour is chiefly sought, and if strength can be got also, so much the better.

There is not the slightest doubt in my mind that unless the teas fit the market they are abused, irrespective of a fair consideration of their merit *sui generis*.

Those who have a system of making and command a fair price, make a mistake in changing

this mode of make. Teas of all kinds are undoubtedly required:—1st flavoury, 2nd strong liquoring, 3rd medium strong and fair liquoring: with every character of appearance can all be made, but flavour and fair strength are now most sought. Everything has to be considered by the planter, quantity *versus* quality for instance, for it takes a terrible high price to make less than 150 lb. an acre pay an estate proprietor. And again if every one tries to make tea identically upon the same lines "character" must cease; for "character" in tea must in a measure be individuality. It would surely be better each man to find out the speciality of his own estate and make accordingly, for if he tries to copy others in a manner in which his estate cannot respond he will be like a dull man trying to be brilliant.

W. F. L.

III.

Agrapatana.

1. June-July very light for young tea in my opinion gives best results. More drastic pruning as tea gets older.

2. Begin by leaving 3 or 4 whole leaves on shoot according to height and strength. When secondary and tertiary flush comes on, leave a whole or half leaf above the bud leaf according to taste; taking tip and two or three leaves.

3. 35 per cent to 40 per cent.

4. Three-quarter firing, leaving for moisture to evaporate a little and then finishing till crisp, has given me best teas. Sifting while firing is not practicable with most driers.

R.

IV.

Ythanside, Kotagala, 22nd July.

All the queries are on points which are or should be generally known. There is no very great difference in the process of tea making, so far as I know, all over the country, unless what is caused by local conditions. Climate and soil determine the yield, care and attention to the work in all its stages will do much to secure a good tea.

Tea making is quite as simple as wasting an egg, no difficulty about the process at all, but, no doubt, everything from plucking to packing must be done at the right time, and no other. Neglect at any stage is fatal to the production of a good article, it *spoil* soon, will not wait, but must not be hurried!—W. C.

V.

4,000 FEET ELEVATION.

In reply to "B."s questions on tea culture and preparation as to pruning, I am of opinion that the actual time of year in which it is done is of little consequence, as any field of fair jāt will continue to flush for over a year after it has received an application of the knife and so is certain to drop in for its share of good flushing weather. I believe the best way to prune is to keep on nearly all the year round a small gang of trained pruners: by this one is saved from those big rushes of leaf which must come on if a large acreage is pruned down at once. The work is done much better and more economically by this mode of work, as each man knows what is expected of him, which cannot always be said when a large gang is turned out to knife the bushes.

Plucking.—The first few rounds after pruning should be plucked at least 6 inches above the pruning level. When the 2nd flushes have started and have grown to 5 leaves, 2½ leaves may be taken, leaving the same number on the bush.

Withering.—About 35 per cent should be lost in withering so as to get the leaf into proper order.

Firing.—I fire by means of Siroccos at a tempera-

ture of 230 deg. and do not sift during firing. The leaf is not kept on the drier until quite crisp but is put in the small bin in a slightly moist condition and will be found quite dry and crisp in a few hours' time, and I have never had any complaints of the tea not keeping well. O. B.

VI.

Your correspondent "A. T." hits the truth with exactness in his opening sentence: "So varied are the conditions," &c.; for as everything depends upon jāt, elevation, soil and exposure, it is impossible to lay down hard written laws; besides, are they not already down in handbooks or in the living handbooks next door to one, whom, and whose handiwork, it is of much more practical benefit to consult than pen-and-ink rules and—theories. Still, if "B." is not one of those who believe that "tea makes itself and is not made" and would like some answers to his questions, here is my experience though it professes no competence.

Estate in Dimbula, 4,000 to 4,500.

PRUNING.—Prune when the bushes require it, low jāt say every 18 months, good jāt every 22, or 24, but *avoid* pruning in June and July. Cut as usual 3 figures above the last, cut to a level, but never mind the level at the edges, should "crow's feet" interfere with its pretty correctness. Below the level cut off all branches that are too thin to produce healthy shoots, but don't touch a healthy branch save to cut it *back* if it drops.

PLUCKING.—I always leave the first leaf and 3 leaves on those primary shoots that rise from the centre of the bush above the cut. The others may require more or less to bring the whole surface to a level. On secondary shoots and succeeding ones 1 leaf, varying this with ½ leaf as the bush gets older. In windblown places doubtless 2 leaves at the start would be sufficient.

WITHERING.—I find that on an average 100 lb. green gives 65 lb. withered leaf. I believe the correct way is to wither as long as possible, without the leaf getting hard or stale.

FIRING.—The non-keeping of Ceylon tea is due I believe to underfermenting, and to the too quick action of our firing machines. I think 220° Fahr. is the best degree, if one has machinery enough. Crisp, yet not too crisp, should the tea be after firing. I have never tried sitting during firing.

Q. L.

B.

TEA YIELD ON OLD COFFEE LAND.

4,000 FEET ELEVATION.

In answer to "W."s letter.

The average age of tea from which first pluckings have been taken would be about two years.

I should put down the average yield per acre to be as follows:—

2 to 3 years old tea	125 lb.	made tea
3 to 4 "	200 lb.	"
4 to 5 "	250 lb.	"
5 to 6 "	275 lb.	"
6 to 7 "	300 lb.	"
7 to 8 "	325 lb.	"

Many individual estates will show a much better return than the above, but with medium plucking I do not think it would be safe to count on a greater average yield from any district of about this elevation.

Tea is generally at its best when about eight years old.

T. R.

C.

Old coffee land is an ambiguous term. Some is wasted and worn; some fresh and good,

Mine is 58 acres coffee land planted in 1871-74, and 4 acres cinchona land planted in 1881. Total 62 acres; elevation 4,400 to 5,000. Tea planted May-August 1884:—

Crop July 1885 to July 1886	..	4,820	lb. leaf.
" 1886 "	1887	..20,188	"
" 1887 "	1888	..50,959	"
" 1888 "	1889	..59,324	"

This last pruned at a wrong season. Q. L.

D.

July 25th, 1889.

SIR,—In answer to your correspondent's question as to what is the yearly percentage of increase of made tea per acre planted on old coffee land, I herewith send you an account from this estate.

There is no doubt about tea paying on old coffee land which gives a yield of 371 lb. per acre at the age of from 5-6 years, and this with medium plucking; when in full bearing this estate should give an average of 300 lb. per acre. A.

Table showing acreage, age, made lb. tea per acre, and yearly percentage of increase per acre:—

Acres.	Age.	Made Tea per Acre.	Percentage of Increase.
21½	4-5	177	—
"	5-6	372	110 per cent.
175½	3-4	96	—
"	4-5	179½	58 "

MADULKELE DISTRICT (about 4,000 feet).

GEMMING IN CEYLON.

Further interesting information on this subject will be found in our columns on the present occasion; and at length we are able to announce an approach to business in the direction we have so long desired to see. A Syndicate of European gentlemen is said to have taken over from a well-known native proprietor in the Gem districts some thousands of acres of land with a view to form a Ceylon Gemming Company; and we have seen a draft prospectus headed the "Rakwana Gemming Company" showing that there are two "Richmonds in the field." We do not see why there should not be half-a-dozen; for certain we are that Ceylon offers a better field for British capitalists than Burma does at the present stage, and yet here is how the *Pioneer* relates the rush after shares in the Burma Company:—

The faith of the public in the Burma Ruby Mines may be judged from a statement made by Sir Lepel Griffin at the general meeting of the Company, to the effect that within a few hours of the issue of 200,000 shares there were applications for 2,762,000. On the other hand Dr. Noetling of the Geological Survey in a letter elsewhere incidentally remarks that he would far rather have shares in Burma Oil Mines than in Burma Rubies.

It is not simply in respect of precious stones that Ceylon presents a good field for the investment of British capital of this time of day; but we can also point to our valuable mineral "plumbago" hitherto mined for solely by natives under very great disadvantages. Several of the plumbago pit owners have lately, however (through the aid of our enterprising local Iron and Engineering House, Messrs. John Walker & Co.), been able to apply pumping and other machinery, and a great improvement may henceforward be expected in the working. Still this exemplifies the primitive style of mining in Ceylon, plumbago having been an important article of export for fully 40 years back, while only now to any great extent is the aid of European machinery called in. In the case of our Gem-pits and the searching for precious stones generally, the ar-

rangements are still of the most primitive character. We wish a full measure of success to the enterprising gentlemen who are promoting the first two Companies likely to occupy the field.

TEA AT 5s. PER LB.—There is a retailer in London who sells tea at 5s. the pound. But then it is "The perfection of tea. In the present rage for cheap tea it may seem extravagant to pay 5s. per pound, although at this price it only costs 5-8ths of one penny per cup, including milk and sugar. The *Standard* of the 10th of September states that, at Uji, in Japan, some teas are valued at 60s a pound. Connoisseurs in tea should try a sample half-pound of Hands' Afternoon Tea, free by post on receipt of Postal Order or stamps for two shillings and sixpence."

A GARDENER'S IDEAS OF COLOMBO VEGETATION.—By the S. S. "Orient" which left our harbour this morning there was Mr. James MacRae proceeding by her as head gardener to His Excellency the Governor of Adelaide, South Australia. Mr. MacRae, who hails from West Prince's Street, Glasgow, was selected amongst a host of applicants to fill up the post, he having served for upwards of ten years in the capacity of gardener under a rich banker in Wall Street, New York; subsequently being employed by Messrs. J. & G. Thomson, the renowned shipbuilders. During his stay in Colombo, he spent the whole of yesterday in visiting Victoria Park, the Cinnamon Gardens, the Fort gardens and all places of interest where a plant or tree was to be found. "Scottie" was very much struck with the beauty of our vegetation, and said that when his present engagement terminated he wished to settle for some time in the hill country of Ceylon.—*Cor.*

BRITISH NORTH BORNEO.—Sandakan, 13th June 1889.—Preparations are in progress for the opening of a number of tobacco estates, amongst them three more on the Kinabatangan and one on the Labuk River. Crop prospects continue good and the general health of labourers considering that so much new forest has been felled and virgin soil disturbed, is very satisfactory. Accounts from some of the estates, however, especially where the managers are far away from direct control, are to the effect that considerable troubles is being caused with their labour force, and on the West Coast the labourers have even absconded in gangs of over a hundred, which, at \$50 for each labourer, is a heavy loss of money, in addition to the loss of their services.—*Correspondent to Hongkong Telegraph.*

TEA PLANTING AND CROPPING.—It is a recognised fact that the tea flush in the districts exposed to the South-West monsoon in Ceylon will always be a poor one, during June, July and August—months when there is generally a good market. This good market may be partly due to the less quantity of tea thus coming forward, and also undoubtedly to the better quality of the tea (in consequence of less quantity?). Now, is there not in this fact of a short supply from the bulk of Ceylon tea districts during, say July and August especially, encouragement to the tea planters in North-East districts, such as Maturata and Uva generally? True, these are dry months on the Eastern side of the mountain ranges; but in Uva there is generally enough of dew to keep the tea bush fit for cropping.—We learn that during the present planting season in South-West districts, planters in many cases with clearings under two years, have been busy pulling out inferior jât plants and supplying with a better quality. This practice of using only first-class plants is likely to be more and more followed in the future: for Ceylon planters have come to understand that 50 acres with a really good jât are better worth having than 100 acres with poor tea.

THE NATURAL HISTORY OF THE TEA TREE,
WITH OBSERVATIONS ON THE MEDICAL
QUALITIES OF TEA, AND ON THE
EFFECTS OF TEA-DRINKING.

A New Edition.

By JOHN COAKLEY LETTSON, M. D., LONDON, 1799.

Advertisement.

In the year 1769 was printed an inaugural dissertation, intitled 'OBSERVATIONES AD VIRES TERRE PERTINENTES.' In the year 1772 was published 'THE NATURAL HISTORY OF THE TEA TREE WITH OBSERVATIONS, &c.,' which not only contained a translation of the Thesis, but likewise the natural history of this vegetable, and which having been long out of print, it was thought a second edition would be favorably received by the public. In Sir George Staunton's Embassy to China, lately published, there are some remarks on Tea, which are occasionally referred to in the present edition; and they are referred to with the satisfaction of confirming the relation first offered to the public in 1772. As the preface inserted at that time affords some hints respecting the introduction of the Tea-tree into Europe, it is prefixed to the present edition.

PREFACE TO THE FIRST EDITION, 1772.—The subject of the following Essay being now in general use among the inhabitants of this Kingdom, as well as in many other parts of Europe, and constituting a large part of our commerce, it cannot but afford pleasure to the curious to possess the history of a shrub, with the leaves of which they are so well acquainted. Many treatises have been published on the uses and effects of tea: a few writers have likewise given some circumstances relative to its natural history and preparation, the indefatigable Kæmpfer particularly; but these circumstances lie so dispersed, and the accounts which have been given of the virtues and efficacy of tea are in general so contradictory and void of true medical observation, that it still seemed no improper subject for a candid discussion. The reader may at least have the satisfaction of seeing, in a narrow compass, the principal opinions relative to this subject. Within these three or four years we have been successful enough to introduce into this Kingdom a few genuine tea plants. There was formerly, I am told, a very large one in England, the property of an East India captain, who kept it some years, and refused to part with either cuttings or layers. This died, and there was not another left in the Kingdom. A large plant was not long since in the possession of the great Linnæus, but, I am informed, it is now dead. I know several gentlemen, who have spared neither pains nor expence to procure this evergreen from China; but their best endeavours have, in general, proved unsuccessful. For, though many strong and good plants were shipped at Canton, and all possible care taken of them during the voyage, yet they soon grew sickly, and but one, till of late, survived the passage to England. The largest Tea-plant in this Kingdom is, I believe, at Kew: it was presented to that royal seminary by John Ellis, Esq., who raised it from the seed. But the plant at Sion House, belonging to the Duke of Northumberland, is the first that ever flowered in Europe; and an elegant drawing has been taken from it in that state, with its botanical description. The engraver has done justice to his original drawing, which is now in the possession of that great promoter of natural history, Dr. Fothergill, to whom I have been indebted for many dried specimens and flowers of the tea-tree from China. If the reader compare this plate with the following description, he will have as clear an idea of this exotic shrub as can at present be exhibited. A few young tea plants have lately been introduced into some of the most curious botanic gardens about London: hence it seems probable that this very distinguished vegetable will become a denizen of England, and such of her Colonies as may be deemed most favourable to its propagation.

In regard to the effects of tea on the human constitution, one might have imagined that long and general use would have furnished so many indisputable proofs of its good and bad properties, that nothing could be

easier than to determine these with precision: yet so difficult a thing is it to establish physical certainty in regard to the operation of food or medicines on the human body, that our knowledge in general, even with respect to this article, is very imperfect. Nevertheless I have endeavoured to avail myself of what has been written on this subject by my predecessors with the appearance of reason, as well as of the conversation of learned and ingenious men now living, together with such experiments and observations as have occurred to me, so as to furnish the means of a more extensive knowledge of the subject.

With respect to the present edition, subsequent information has enabled me to enlarge it with some important additions. Since the period of the original publication, the tea-tree has been introduced into many of our gardens, and afforded the means of ascertaining its botanical characters. I have at the same time the pleasure to observe, that the first edition has received the approbation of some of the most distinguished botanists. Linnæus, as well as Haller, as soon as they had perused it, conveyed to me their approbation in the kindest manner: Murray and Cullen, and recently Schreber, have made frequent references to its authorities. If these distinguished characters have approved the former, I am encouraged to hope that the present edition will not be less favourably received by the public.

Contents.

Part I.—THE NATURAL HISTORY OF THE TEA TREE.

- Section I. Class and Order.
- II. Synonyms.
- III. Authors upon Tea.
- IV. Origin of Tea.
- V. Soil and Culture.
- VI. Gathering the Leaves.
- VII. Method of Curing or Preparing Tea.
- VIII. Varieties of Tea.
- IX. Drinking of Tea.
- X. Succedanea.
- XI. Preserving the Seeds for Vegetation.

Part II.—THE MEDICAL HISTORY OF TEA.

NOTES.—Among several hundred specimens of dried Tea flowers that I have examined, scarcely one in twenty was perfect. Some had three petals only, some nine, and others the several intermediate numbers. The greatest number consisted of six large petals, and externally three lesser ones of the same form. But the flowers which blossomed on the tea-plant belonging to the Duke of Northumberland, from which this description is taken, consisted in general of six petals. One of the flowers indeed appeared to have eight petals: however, the number in the flowers in most plants vary considerably, which may account for the mistake of Dr. Hill, and Professor Linnæus (who described this plant on Dr. Hill's authority) who make the green and bohea tea two distinct species, giving nine petals to the former, and six to the latter.

In a flower I received from that accurate naturalist, J. Ellis, F. R. S. &c., I counted upwards of 280 filaments; and in another I had from Dr. Fothergill, there appeared to be nearly the same number.

Authors differ widely respecting the size of this tree. Le Comte says, it grows of various sizes from two feet to two hundred, and sometimes so thick that two men can scarcely grasp the trunk in their arms: though he afterwards observes, that the tea-trees he saw in the province of Fokien did not exceed five or six feet in height. (Journey through the Empire of China. London, 1697. 8vo. p. 228.) Du Haide quotes a Chinese author who describes the height of different tea-trees from one to thirty feet. But Kæmpfer, who is chiefly to be depended upon, confines the full growth to about a man's height. Probably this may be a just medium; for Osbeck says that he saw tea-shrubs in flower-pots not above an ell high.

Whether the word TEA is borrowed from the Japanese *Tsjaa*, or the Chinese *Theh* is not of much importance. By this name with very little difference in pronunciation the plant here treated of is well known in most parts of the world.

There is only one species of this plant; the difference of green and bohea tea depending upon the nature of the soil, the culture, and the manner of drying the leaves. It has even been observed that a green tea-tree planted in the bohea country will produce bohea Tea and so the contrary. I have examined several hundred flowers both from the bohea and green tea countries, and their botanical characters have always appeared uniform. See Directions for bringing over seeds and plants, by John Ellis, Esq. Sir George Staunton's Embassy, Vol. II. p. 464, says, "Every information received concerning the tea-plant concurred in affirming that its qualities depended upon the soil in which it grew and the age at which the leaves were plucked off the tree, as well as upon the management of them afterwards.

[Here follows the list of 'Authors upon Tea,' and in a note to one of them, "Translation in English of Giovanni Botaro, an eminent Italian author. Printed in 1590" Lettsom says] "The writer observes that the Chinese have also a herb out of which they press a delicate juice which serves them for a drink instead of wine: it also preserves their health and frees them from all those evils 'that the immoderate use of wine doth breed into us.' By the use the modern Chinese make of tea (who are a sober people) it can be nothing else."

SECTION IV.—ORIGIN OF TEA.

As China and Japan are the only two countries known to us where the Tea Shrub is cultivated for use, we may reasonably conclude that it is indigenous to one of them if not to both. What motive first led the natives to use an infusion of tea in the present manner is uncertain: but probably in order to correct the water which is said to be brackish and ill-tasted in many parts of those countries. Of the good effects of tea in such cases we have a remarkable proof in Kalm's journey through N. America, which his translator gives us in the following words:—"Tea is differently esteemed by different people, and I think we would be as well and our purses much better if we were without tea and coffee. However, I must be impartial, and mention in praise of tea that if it be useful it must certainly be so in summer on such journeys as mine through a desert country where one cannot carry wine or other liquors, and where the water is generally unfit for use, as being full of insects. In such cases it is very pleasant when boiled, and tea is drunk with it: and I cannot sufficiently describe the fine taste it has in such circumstances. It relieves a weary traveller more than can be imagined as I have myself experienced, together with a great many others who have travelled through the desert forests of America: on such journeys it is found to be almost as necessary as victuals."

About the year 1600 Texeira, a Spaniard, saw the dried tea leaves in Malacca, where he was informed that the Chinese prepared a drink from this vegetable: and in 1633 Olearius found this practice prevalent among the Persians, who procured the plant under the name of *Cha orchia*, from China by means of the Usbeck Tartars. In 1639 Starkaw the Russian Ambassador at the court of the Mogul, Chan Altyn, partook of the infusion of tea; and at his departure was offered a quantity of it as a present for the Czar Michael Romanof, which the Ambassador refused as being an article for which he had no use.

This article was first introduced into Europe by the Dutch East Indian Company very early in the last century; and a quantity of it was brought over from Holland about the year 1666* by Lord Arlington and

* Harway's Journal of Eight Days' Journey, vol. ii. p. 21. The same author observes that tea sold at this time for sixty shillings a pound. Anderson in his 'Chronological Deduction of Commerce' remarks that the first European author that mentions tea wrote in the year 1590. However, by the preceding catalogue it will appear that this subject had been considered much earlier. In *Renaudot's anciennes Relations*, Paris, 1718, p. 31, mention is made of two Arabian travellers who visited China about the year 850, and related that the inhabitants of that empire had a medicinal beverage named *chah* or *sah*, which was prepared by pouring boiling water on the dried leaves of a certain herb, which infusion was ekoned an efficacious remedy in various diseases.

Lord Offory. In consequence of this tea soon became known amongst people of fashion, and its use by degrees since that period has become general.

It is however certain that before this time drinking tea, even in public coffee-houses, was not uncommon; for in 1660 a duty of four pence per gallon was laid on the liquor made and sold in all coffee-houses.*

So early as 1678 Cornelius Bontekoe, a Dutch physician, published a treatise in his own language on tea, coffee, and chocolate. In this he shows himself a very zealous advocate for tea, and denies the possibility of its injuring the stomach although taken to the greatest excess as far as one or two hundred cups in a day (!). To what motive we are to impute the partiality of Dr. Bontekoe is uncertain at this period; but as he was first physician to the Elector of Brandenburg, and probably of considerable eminence and character, his eulogium might tend greatly to promote its use; however, we find its importation and consumption were daily augmented; and before the conclusion of the last century it became generally known among the common people in England.

It is foreign to my subject, or it would perhaps afford to a speculative mind no inconsiderable satisfaction to trace the consumption from its first entrance at the Custom-house to the present amazing imports. At this time upwards of twenty-three millions of pounds are annually allowed for home consumption; and the East India Company have generally in their warehouses a supply at least for one year.

It is probable that the Dutch as they traded considerably to Japan about the time tea was introduced into Europe first brought this article from thence. But now China is the general mart, and the province Fokien, or Fo-chen, the principal country that supplies both the Empire and Europe with this commodity.

SECTION V.—SOIL AND CULTURE.

To the ingenious Kämpfer we are principally indebted for any accurate information respecting the culture of the tea-tree; and as his account was composed during his residence at Japan, greater credit is certainly due to it. We shall give what he says upon this subject, and then state the accounts we have been able to collect of the Chinese method. Kämpfer tells us that no particular gardens or fields are allotted for this plant, but that it is cultivated round the borders of rice and cornfields without any regard to the soil. Any number of the seeds, as they are contained in their seed vessels, not usually less than six, or exceeding twelve or fifteen, are promiscuously put into one hole, made four or five inches deep in the ground at certain distances from each other. The seeds contain a large proportion of oil which is soon liable to turn rancid; hence scarce a fifth part of them germinate, and this makes it necessary to plant so many together. The seeds vegetate without any other care, but the more industries annually remove the weeds and manure the land. The leaves which succeed are not fit to be plucked before the third year's growth, at which period they are plentiful, and in their prime. In about seven years the shrub rises to a man's height; but as it then bears few leaves, and grows slowly, it is cut down to the stem which occasions such an exuberance of fresh shoots and leaves the succeeding summer as abundantly compensates the owners for their former loss and trouble. Some defer cutting them till they are of ten years' growth. So far as can be gathered from authors and travellers of credit, this shrub is cultivated and prepared in China in a similar manner to what is practised in Japan; but as the Chinese export considerable quantities of tea, they plant whole fields with it to supply foreign markets as well as for home consumption.

* By an act made this year the duties of Excise on malt liquor, cyder, perry, mead, spirits, or strong waters, coffee, tea, sherbet, and chocolate were settled on the King during his life. Then it was that coffee, tea, and chocolate were first mentioned in the Statute-book. In May 1784 an Act was passed, called the Commutation Act, "for repealing the several duties on tea, and granting to his Majesty other duties in lieu thereof; and also several duties on inhabited houses."

The tea tree delights particularly in valleys, or on the declivities of hills, and upon the banks of rivers, where it enjoys a southern exposure to the sun, though it endures considerable variations of heat and cold as it flourishes in the northern clime of Pekin, as well as about Canton,* the former of which is in the same latitude as Rome; and from meteorological observations it appears that the degree of cold about Pekin is as severe in winter as in some of the northern parts of Europe.

SECTION VI.—GATHERING THE LEAVES

At the proper seasons for gathering the tea leaves, labourers are hired who are very quick in plucking them, being accustomed to follow this employment as a means of their livelihood. They do not pluck them by handfuls, but carefully one by one; and tedious as this may appear, each person is able to collect from four to ten or fifteen pounds in one day. The different periods in which the leaves are usually gathered are particularly described by Kœmpfer.

I. The first commences at the middle of the last moon immediately preceding the vernal equinox, which is the first month of the Japanese year, and falls about the latter end of our February or beginning of March. The leaves collected at this time are called Ficki Tsjaa, or powdered tea, because they are pulverised and sipped in hot water. These tender young leaves are but a few days old when they are plucked; and because of their scarcity and price are disposed of to princes and rich people only; and hence this kind is called Imperial Tea. A similar sort is also called Udsi Tsjaa and Packe Sacki Tsjaa from the particular places where it grows. The peculiar care and nicety observed in gathering the tea leaves in these places deserve to be noticed here, and we shall therefore give some account of one of them. Udsi is a small Japanese town bordering on the sea and not far distant from the city of Miaco. In the district of this little town is a pleasant mountain of the same name, which is thought to possess the most favorable soil and climate for the culture of tea, on which account it is enclosed with hedges, and likewise surrounded with a broad ditch for farther security. The trees are planted upon this mountain in such a manner as to form regular rows with intervening walks. Persons are appointed to superintend the place and preserve the leaves from injury or dirt. The labourers who are to gather them for some weeks before they begin to abstain from every kind of grass food or whatever might endanger communicating any ill-flavour to the leaves; they pluck them also with the same delicacy having on a thin pair of gloves. [The same cautions are not observed previous to collecting other sorts of tea.] This sort of Imperial or bloom tea is afterwards prepared, and then escorted by the chief surveyor of the works of this mountain, with a strong guard and a numerous retinue to the Emperor's court for the use of the Imperial family.

II. The second gathering is made in the second Japanese month about the latter end of March or beginning of April. Some of the leaves at this period are come to perfection, others not arrived at their full growth; both, however, are promiscuously gathered, and are afterwards sorted into different classes, according to their age, size, and quality; the youngest particularly are carefully separated, and are often sold for the first gathering or Imperial tea. The tea collected at this time is called Tootijaa, or Chinese Tea,

* The best tea grows in a mild temperate climate; the country about Nankin producing better tea than either Pekin or Canton, between which places it is situated. It has been asserted that no tea plants have yet died in England through excess of cold, but the contrary I know has happened. The plant in the Princess Dowager's garden at Kew flourished under glass windows with the natural heat of the sun, as now do those at Mile End in the possession of the intelligent botanist, J. Gordon. The tea plant belonging to Dr. Fothergill thrives in his garden at Upton exposed to the open air, and the plant introduced into the Botanic Garden at Chelsea had one leaf which measured five inches and a quarter in length.

because it is infused and drank after the Chinese manner. It is divided by the tea dealers and merchants into four kinds, distinguished by as many names.

III. The third and last gathering is made in the third Japanese month which falls about our June, when the leaves are very plentiful and full-grown. This kind of Tea, called Ban Tsjaa, is the coarsest, and is chiefly drunk by the lower class of people. Some confine themselves to two gatherings in the year, their first and second answering the preceding second and third. Others have only one general gathering,* which they make also at the same time with the preceding third or last gathering; however, the leaves collected at each time are respectively separated into different sortments. The Chinese collect the tea at certain seasons, but whether the same as in Japan, we are not so well informed; most probably, however, the tea harvest is nearly at the same periods, as the natives have frequent intercourse, and their commercial concerns with each other are very extensive.

SECTION VII.—METHOD OF CURING OR PREPARING TEA IN JAPAN.

Public buildings, or drying-houses, are erected for curing tea, and so regulated that every person, who either has not suitable conveniences, or wants the requisite skill may bring his leaves at any time to be dried. These buildings contain from five to ten or twenty small furnaces about three feet high, each having at the top a large flat iron pan, either high, square, or round, bent up a little on that side which is over the mouth of the furnace, which at once secures the operator from the heat of the furnace, and prevents the leaves from falling off. [Some writers mention copper pans, and suppose that the green efflorescence which appears on copper may increase the verdure of green tea; but from experiments that I made there does not appear any foundation for this supposition.] There is also a long low table covered with mats, on which the leaves are laid, and rolled by workmen, who sit round it. The iron pan being heated to a certain degree by a little fire made in the furnace underneath, a few pounds of the fresh-gathered leaves are put upon the pan; the fresh and juicy leaves crack when they touch the pan, and it is the business of the operator to shift them as quick as possible with his bare hands till they grow too hot to be easily endured. At this instant he takes off the leaves with a kind of shovel resembling a fan and pours them on the mats to the rollers, who, taking small quantities at a time, roll them in the palms of their hands in one direction, while others are fanning them that they may cool the more speedily, and retain their curl the longer. [Sir G. Staunton, Embassy to China, observes that the tea leaves are each rolled separately between the fingers of a female. Vol. ii, p. 465.] This process is repeated two or three times, or oftener before the tea is put in the stores in order that all the moisture of the leaves may be thoroughly dissipated, and their curl more completely preserved. On every repetition the pan is less heated, and the operation performed more slowly and cautiously. [This should be carefully attended to in curing the fine green teas, to preserve their verdure and perishable flavour.] The tea is then separated into the different kinds, and deposited in the store for domestic use or exportation.

As the leaves of the Ficki Tea are usually reduced into a powder before they are drunk, they should be roasted to a greater degree of dryness. As some of these are gathered when very young, tender, and small, they are first immersed in hot water, taken out immediately, and dried without being rolled at all. Country people cure their leaves in earthen kettles, which answer every necessary purpose at less trouble and expense, whereby they are enabled to sell them cheaper. To complete the preparation, after the tea has been kept some months, it must be taken out of the vessels, in which it had been contained, and dried again over a very gentle fire that it may be deprived of any humidity which remained, or might since have been contracted. The common

* In this case the tender leaves, which are harsh and less succulent, are probably left upon the trees.

tea is kept in earthen pots with narrow mouths; but the best sort of tea used by the Emperor and nobility is put in porcelain or China vessels. The Bantsjaa, or coarsest tea, is kept by the country people in straw baskets, made in the shape of barrels, which they place under the roofs of their houses, near the hole that lets out the smoke, and imagine that this situation does not injure the tea. This is the relation we have from Kämpfer of the method in which the Japanese collected and cured their tea. In the accounts of China, authors have in general treated very slightly of the cultivation and preparation of tea. Le Compte, indeed, observes that to have good tea, the leaves should be gathered while they are small, tender, and juicy. They begin commonly to gather them in the months of March and April, according as the season is forward; they afterwards expose them to the steam of boiling water to soften them, and as soon as they are penetrated by it, they draw them over copper plates, kept on the fire, which dries them by degrees, till they grow brown, and roll up of themselves in that manner we see them. However, it is certain from the Chinese drawings, which exhibit a faithful picture, though rudely executed, of the whole process from beginning to end, that the tea tree grows for the most part in hilly countries, on their rocky summits and steep declivities; and it would seem by the pains the Chinese are at in making paths and fixing a kind of scaffold to assist them, that these places afford the finest tea. It appears from these drawings that the trees in general are not much taller than man's height: the gatherers of the leaves are never represented but on the ground; they make use of hooked sticks indeed, but these seem rather intended to draw the branches towards them when they hang over brooks, rivers, or from places difficult of access, than to bend down the tops or upper branches of the trees on plain ground. They pick the leaves as soon as gathered into different sorts, and cure them nearly in the manner described to be practised by the Japanese. They build a range of stoves like those in a chemist's laboratory, or great kitchen, where the men work and curl the leaves in the pans themselves. It seems also that they repeat the drying. They dry it likewise after having spread it abroad in shallow baskets in the sun; and by the means of sieves separate the larger from the smaller leaves, and these again from the dust.

The Chinese put the finer kinds of tea into conic vessels like sugar loaves made of tutenague, tin, or lead, covered with neat matting of bamboo; or in square wooden boxes lined with thin lead, dry leaves and paper, in which manner it is exported to foreign countries. The common tea is put into baskets, out of which it is emptied, and packed up in boxes or chests as soon as it is sold to the Europeans. [There are several disgusting circumstances attending the preparation of tea. Osbeck says the Chinese servants tread the tea into the chests with their naked feet.] One thing should be mentioned to their credit; when their harvest of tea is finished, each family fails not to testify by some religious rite their gratitude to the Giver.

SECTION VIII.—VARIETIES OF TEA.

It has been already observed that many different sorts of tea are made during the times of collecting the leaves, and these are multiplied according to the goodness of their preparation, by which the varieties of tea may be considerably augmented. The distinctions with us are much more limited being generally confined to three principal kinds of green, and five of bohea. I. Those of the former are:— 1. Bing, Imperial, or bloom tea, with a large, loose leaf, of a light green colour, and faint delicate smell. 2. Hy-tiann, hi-kiong, or hayssuen, known to us by the name of Hyson tea, so called after an East Indian merchant of that name, who first imported it into Europe. The leaves are closely curled and small, of a green colour, verging towards blue. [The Chinese have another kind of Hyson tea, which they call Hyson-Utchin, with narrow short leaves. Another sort of green tea they name Go-bé, the leaves of which are narrow and long.] 3. Single, or songlo, which name it receives like many other teas from the place where it is cultivated.

II.—THE BOHEA TEAS.

1. Soochuen, or Sutchong, by the Chinese called Saatyang, and Saet-chaon, or Su-tyann, is a superior kind of long-fou tea. It imparts a yellowish green colour by infusion. [Padre sutchong has a finer taste and smell than the common sutchong. The leaves are large and yellowish, not rolled up, but expanded, and packed up in papers of half a pound each. It is generally conveyed by caravans into Russia. Without much care it will be injured at sea. This tea is rarely to be met with in England.] 2. Camho, or Soumlo, called after the name of the place where it is gathered: a fragrant tea with a violet smell. Its infusion is pale. 3. Cong-fou, congo, or bong-fo. This has a larger leaf than the following, and the infusion is a little deeper coloured. It resembles the common bohea in the colour of the leaf. [There is a sort of tea called lin-kisam with narrow rough leaves. It is seldom used alone, but mixed with other kinds. By adding it to congo, the Chinese sometimes make, a kind of pekoe tea.] 4. Pekao, pecko, or pekoe, by the Chinese called back-ho, or pack-ho. It is known by having the appearance of small white flowers intermixed with it. 5. Common bohea, called maji by the Chinese, consists of leaves of one colour. [The best bohea tea is named by the Chinese tao-kyonn. An inferior kind is called An-kai from a place of that name. In the district of Honam, near Canton, the tea is very coarse, the leaves yellow or brownish, and the taste the least agreeable of any. By the Chinese it is named Honam té or Kuli té.]

III. There has also been imported a sort of tea, in balls of a different form from any of the preceding, made up into cakes or balls of different sizes, by the Chinese called Poncul-toha. 1. The largest kind of this cake tea that I have seen weighs about two ounces: the infusion and taste resemble those of good bohea tea. 2. Another sort, which is a kind of green tea, is called tis té: it is rolled up in a round shape, about the size of peas, and sometimes as large as a nutmeg. 3. The smallest kind done in this form is called Gunpowder tea. 4. Sometimes the succulent tea leaves are twisted into cords like pack thread, about an inch and a half or two inches long: and usually three of these are tied together at the ends by different coloured silk threads. These resemble little bavons, one of which might suffice for tea for one person. I have seen them both of green and bohea tea.

The Chinese likewise prepare an extract from tea which they exhibit as a medicine dissolved in a large quantity of water, and ascribe to it many powerful effects in fevers and other disorders when they wish to procure a plentiful sweat. This extract is sometimes formed into small cakes, not much broader than a sixpence, sometimes into rolls of a considerable size. That there is only one species of tea tree has already been mentioned, from which all the varieties of tea are procured. Kämpfer, who is of this opinion, attributes the difference of teas to the soil and culture of the plant, age of the leaves when gathered, and method of curing them. These circumstances will severally have more or less influence, though whether they account for all the varieties observable in tea may be doubted. The bohea tea trees now introduced into many botanic gardens near London exhibit very obvious varieties. The leaves are of a deeper green colour, and not so deeply serrated: the stalk is usually of a darker colour, and the whole shrub appears less luxuriant than that represented in the annexed plate of the bohea tea: but the botanical characters are the same. I infused all the sorts of green and bohea teas. I could procure, and expanded the different leaves on paper, to compare their respective size and texture, intending thereby to discover their age. I found the leaves of green tea as large as those of bohea, and nearly as fibrous: which would lead one to suspect that the difference does not so much depend upon the age as upon other circumstances. We know that in Europe the soil, culture, and exposure have great influence on all kinds of vegetables; but the same species of plants differ in the same province, and even in the same district; and in Japan

and particularly along the continent of China, it must be much more considerable where the air is in some parts very cold, in others moderate, or warm almost to an extreme. I am persuaded that the method of preparation must also have no little influence. I have dried the leaves of some European plants in the manner described, which so much resembled the foreign tea, that the infusion made from them has been seen and drunk without suspicion. In these preparations which I made, some of the leaves retained a perfect cure, and a fine verdure like the best green tea; and others cured at the same time were more like the bohea. [A certain moderate degree of heat preserved the verdure and flavour better than a hasty exsiccation. In the first case it is necessary to repeat the roasting oftener.] I would not, however, lay too much stress upon the result of a few trials, nor endeavour to preclude further enquiries about a subject which at some future period may prove of more immediate concern to this nation. We might still try to discover whether other arts than are yet known here are not used with tea before its exportation from China, to produce the difference of colour and flavour peculiar to different sorts. [Infusions of fine bohea teas do not differ a great deal in colour from those of green. To spirit they equally impart a fine deep green colour. I am informed by intelligent persons who have resided some time at Canton that the tea about that city affords very little smell whilst growing. The same is observed of the tea plants in England, and also of the dried specimens from China. We are not hence to conclude that art alone conveys to teas when cured the smell peculiar to each kind: for our vegetables, grasses for instance, have little or no smell till dried, and made into hay.] An intelligent friend of mine informs me, that in a set of Chinese drawings in his possession, representing the whole process of manufacturing tea, there are in one sheet the figures of several persons apparently separating the different kinds of tea, and drying it in the sun, with several baskets standing near them filled with a very white substance and inconsiderable quantity. To what use this may be applied is uncertain, as well as what the substance is: yet there is no doubt, he thinks, that it is used in the manufacturing of tea, as the Chinese seldom bring anything into their pieces but such as relate in some respect to the business before them. We are better acquainted with a vegetable substance which has been employed by the Asiatics in giving a flavour to tea. This is the *Olea Fragrans*, whose flowers are frequently to be met with in teas exported from China.

As green tea is by some suspected to have been cured on copper, they have attributed the verdure to be derived from that metal; but if there were any foundation for this supposition, the volatile alkali mixed with an infusion of such tea would detect the least portion of copper by turning the infusion blue. [The hundredth part of a grain of copper dissolved in a point of liquor strikes a sensible blue with volatile alkalies. The finest imperial and bloom teas showed no sign of the presence of this metal by experiment.] Others have, with less propriety, attributed the verdure to green copperas, but this ingredient, which is only salt of iron, would immediately turn the leaves black, and the infusion made from the tea would be of a deep purple colour. It is not more probable that some green dye prepared from vegetable substances is used for the colouring. [“It is confidently said in the country that no plates of copper are ever employed for that purpose. Indeed scarcely any use is used in China is of that metal, the chief application of which is for coin. The earthen or iron plates are placed over a charcoal fire, which draws all remaining moisture from the leaves, rendering them dry and crisp.” Sir G. Staunton’s Embassy, Vol. II. p. 465.]

SECTION X.—SUCCEDANEA.

Curiosity and interest would mutually induce the Europeans to make the most diligent enquiries in order to discover the real tea shrub, or a substitute in some other vegetable most resembling it. Simon

Pauli, a celebrated physician and botanist at Copenhagen, was the first who pretended to have discovered the real tea plant in Europe. By opening some tea leaves, he found them so much like those of the Dutch myrtle,* that he obstinately maintained they were productions of the same species of tea, though he was afterwards refuted by several botanists in Europe, and by the specimens sent to him, and to Dr. Mentzel of Berlin from the East Indies, by Dr. Clever.

Father Labat next thought he had discovered the real tea plant in Martinico, agreeing he says in all respects with the China sort. He pretends also to have procured tea seeds from the East Indies, and to have raised the plant in America, but from his own account, this supposed tea appears to be only a species of *Lysimachia*, or what is called West Indian tea.

Many other pretended discoveries of the Oriental tea tree have been related; all of which have proved erroneous, when properly enquired into. The genus of plant, called by Kämpfer *Tsubakki*,† has the nearest resemblance to it. The leaves of several European herbs have been used at different times as substitutes for tea, either from some similarity in the shape of the leaves, or in the taste and flavour; among these, two or three species of *Veronica* are particularly recommended, besides the leaves of sage, myrtle, betony,‡ sloe,§ agrimony, wild rose, and many others. Whether any of these are really more salutary or not, is undetermined; and we now find that from the palace to the cottage every other substitute has yielded to the genuine Asiatic tea.

COCONUT PLANTING.—I cannot conceive why more planters in the island don’t turn their attention to coconuts. Many doubtless are quite unable, but surely there are some who see the good to be received from having two strings to one’s bow and are quite able to go in for both tea and coconuts for some time?—*Cor.*

* *Myrtica Gale*, Gohle, Sweet Willow, or Dutch Myrtle. A plant of peculiar fragrance found in the north of England, Brabant, and other northern countries. Simon de Molingris was the first who opposed this opinion of Simon Pauli, by shewing the difference betwixt this species of Myrtle and the oriental tea.

† Two specimens of this plant are now in the physic garden at Upsal. About the year 1755, they were brought over from China by M. Lagerstrom, a Director of the Swedish East India Company, under the supposition of being tea plants, till they appeared in blossom, when they proved to be this species of *Tsubakki*, called by Linnaeus, *Camellia*. This celebrated naturalist says:—“That the leaves of his *camellia* are so like the true tea, that they would deceive the most skilful botanist, the only difference is that they are a little broader.” A *camellia* was brought in 1771 from China in good health; the leaves of this shrub end in a double obtuse point (obtusely emarginated) like those of the tea tree, which makes them still more liable to be mistaken for those of the latter. Kämpfer observes that the leaves of a species of *Tsubakki* are preserved and mixed with tea to give it a fine flavour. It is now a common plant in the greenhouses about London.

‡ Botanical writers celebrate this herb for its many virtues; hence arose the Italian proverb “*Vende latonica, et compra la Betonica* (sell your tonics, and buy betony).”

§ In the year 1776 an Act was passed for the more effectual prevention of the manufacturing of ash, elder, sloe, and other leaves, in imitation of tea: and to prevent frauds in the revenue of Excise in respect to tea, 17 George III. chap. 29, being an amendment of the Act 4 George II., intituled “An Act to prevent fraud in the Revenue of Excise with respect to Starch, Coffee, Tea, and Chocolate.

Correspondence.

To the Editor.

COOLIE LIFE IN SUMATRA.

Sumatra, 5th July 1889.

DEAR SIR,—Your book "All About Tobacco Planting" is to hand, for which many thanks. In looking it over, I notice at page 196 an article—"Experience of Coolie Life in Sumatra." You mention you are unaware of the author. The solution is easy and as a tribute to a man who always did his duty in the face of many difficulties, I shall feel obliged if you will mention his name. The article was written by my brother James Hertz Zadick Just, and printed by a China newspaper. He was for many years in the employ of the Deli Maatschappij, and one of the many pioneers in planting, who have, alas, passed away. My father had the article printed as a small brochure some years ago, and if you want a copy as verification of this statement you can get one. He was a careful observer, and what is written can be relied on. Mr. H. Herring of Assahan has a copy of the pamphlet.—I remain, yours truly,

A. W. JUST.

[We are obliged to our correspondent for the information he gives: we should certainly like to see a copy of the brochure in question.—Ed.]

YIELD OF TEA IN OLD COFFEE LAND:—
REPLY No. I.

SIR,—In reply to "W"'s enquiry as to yield of tea on old coffee land I give my experience:—first tea planted June 7th 1884, first plucking October 1885, mere tipping to keep bushes down: Crop Oct. 1885 to June 1886=1,775 lb.

Crop 1886-87.—Half estate pruned July-August rather too severely=16,574 lb.

Crop 1887-88.—The other half lightly pruned in June-July=40,349 lb.

Crop 1888-89.—The first half lightly pruned again June-July=96,320 lb.

206 acres were plucked from first year, 226 second year and 237 the third year. R.
[About 4,000 feet elevation?—Ed.]

PADDY CULTIVATION IN BATTICALOA.

Batticaloa, Kalmunai, 5th July 1889.

DEAR SIR,—The Government Agent, Mr. E. Elliott, who has at heart the welfare of the people of this province, without any reference to their class, language or creed, convened a grand meeting to decide the question of paddy cultivation and irrigation in this ancient granary of Ceylon, and to appoint first of all a right and proper man as the Irrigation Officer of Sammanturrai Patu.

This large meeting was held on Tuesday, the 2nd of July 1889. Among several other important matters publicly discussed and decided by him, one was to consider who is a competent Vanniyar to distribute the tank water to Chadayatolalai fields fairly and justly to all cultivators alike, fixing proper season for sowing them with suitable paddy, according to high or low situation of different fields.

Ed manasinga Vanniyar of Sammanturrai Patu was fitly elected as a right man in the right place, and approved by the Government Agent who has placed the impetuous and youthful Venisatamby Sinnatamby Vanniar of the central division of this district under the former's general guidance and advice and ordered him not to have any thing to do with Dr. Covington's fields, quashing all his proceedings against his cultivators and remitted also the fine imposed by him on them

All present, with the exception of a few friends and adherents of Sinnatamby Irrigation Vanniyar, admired and applauded Mr. Elliott's firm, just and impartial decisions on several important matters on this occasion.

The weather here now is alternately wet and dry. The harvest in general good. Paddy is cheap and people sell it for R7-50 an ammunam of good paddy or 3 fanams a muracal. Coconuts only are very dear.—I am, dear sir, yours very truly,
M. COVINGTON.

THE AMERICAN TEA CO.—WHY ALL TEA
PLANTERS SHOULD TAKE SHARES.

Holmwood, Agra Patana, 18th July 1889.

SIR,—Those who object to take shares in the American Co. on the grounds that they do not see any return for their money, forget that unless the whole scheme is an utter failure the pushing of our teas in America must surely keep prices one cent per lb. higher than they would be without it. This means R1,000 per annum to every man who turns out 100,000 lb. from his factory. Is this no return for our money? One cent per lb. will mean R500,000 per annum to Ceylon soon. The more we advertise the more cents per lb. shall we add. Let everyone who has a factory think of one cent per lb. extra and take a few shares to help the Ceylon Advertisement even if he sees no prospective dividend, though many are confident of a good one eventually. Yours, &c. E. W. W.

"MR. BORRON; BARBECUE PLANTING;
AND COTTON."*

DEAR SIR,—Since Mr. B. abandoned cotton to its fate, and raked up an old story, he has written three letters, against two from me. I think, on that ground, as well as because of the desperate recklessness of his assertions, I may claim space for another. I notice that, what in his second letter he admitted was quite possible, is now, when supported by my affidavit *utterly false*. The reason is obvious he was not certain when writing the second, that I had not preserved his letter expressing deep "concern etc." He has as usual evaded my question as to why, believing me to be grossly dishonest, he insisted on numbering me amongst his friends. We now know on what principle he chooses friends. I am glad that on further probation, I am found wanting. It is difficult to deal with one who disregarding decency, reason and probability takes his cue from the habits of his coolies. As a proof of the difficulty, I may mention that one gentleman writing from an upcountry district, says "spare the poor—," while a neighbour, writing from within 2 miles of the former, urges stronger battle and offers assistance! I think the general verdict may well be summed up on the words of a third.—"He pretends to think he has crushed you, whereas really he has only evaded."

I have gone over Mr. B.'s letters to see whether there is any definite point unanswered. I find only one, that on which he bases the charge of malevolence. Let your readers judge whether he has made a mountain out of a mole heap. He says when he wrote of "such a Government," he did not write *such* in small capitals, whereas I have done so. But the "such" having obtained so great notoriety for itself and its author, I think I could not refer to it in another dress than italics and capitals. I submit that this is a fair sample of the foundation of all his charges. David in his wrath said all men are liars. For David when sick, a breathing soothing solace was prescribed. Mr. B. should take note of this; it is bad for man to be alone.

The subject of barbecue planting was being discussed a few days ago in a rest-house, when I suggested that if Mr. B. had even been more than a philosophic dreamer, it might have occurred to him, that under-

* Heading by the writer of the letter.—Ed.

neath the concrete of the old barbecue lay perhaps the only sample of the original vegetable mould and humus, on *old Hantane*, all else being washed away years ago. A gentleman present, observed that on a group of estates which he had managed, the best tea was growing on an ancient barbecue site. Be comforted G. P. I don't think Peppercorn need fear a stirring of the dry bones against him, should he say anything he knows about cotton. After each discharge I have noticed a certain volcano lies quiet for a year or two. I think those who have any information it give may speak out fearlessly, there is now no lion on the path.

The experiment being made by my friends and me, has been disappointing so far; but not discouraging, as circumstances have probably been against it. We intend to persevere. But unless as an annual, planted that the pods may open in February, the Kelani Valley is too wet for cotton. Even then the chances in its favour, and profits if successful, are not such as to induce men to incur the risk of failure. I have had verbal accounts of several experiments in the drier planting districts, and am promised them in writing, when you may again hear from me. It would be a great pity if the "damning with faint praise" of its advocate, should tend to check attempts to grow the bantling. I cannot help hoping, nay believing that there is a wide field for it in Ceylon, though perhaps not in the tea districts. An experiment on a large scale is to be made in Dumbara, by a man who will give it every justice. I truly hope he may succeed.

W. McK.

[In regard to the personal part of this letter we had certainly hoped that the "battle-royal" was closed with the last very brief letter from the other side, and we said as much in answer to complaints. We had previously intimated our opinion to both gentlemen that the controversy had already gone too far and that he would act the more dignified part who would *not* insist on "the last word."—We are glad to see what is said above of further experiments with cotton and trust to hear of successful results not only in Dumbara but in Matale and elsewhere.—Ed.]

TEA CULTURE AND PREPARATION: ANSWERS TO QUESTIONS BY "B."—No. I.

SIR,—So varied are the conditions under which tea is cultivated in Ceylon, that only the most general principles can adequately be applied, or proved. Before therefore, discussing the questions asked by your correspondent, it is necessary to mention a few characteristics more or less local and controlling the aptness of the answers. The estate is situated from 2,000 to 4,400 feet above the sea level, the land is precipitous and exposed to fierce wind during the South-West monsoon. The rainfall is about 180 inches, well distributed but heaviest in July and December. The best flushing months are February, March, April, and October, comparatively little leaf being got in July August, December and January. The tea is all in full bearing, and the *jât* medium and poor.

PRUNING.—The best time to prune is when the bushes are doing best, provided, if pruned then, they will not suffer from drought before they have had time to form, or from wind while the primary shoots are green. As pruning the total acreage at one time would incur serious labour difficulties and cause an abnormal rush of crop, necessitating an unnecessary outlay in stores and machinery, and consequent increase in cost of production, it is advisable to prune only a third or thereby of the acreage at one time. Under ordinary circumstances tea will flush fairly well for 18 months; and by pruning a third in July, and a third in December, a species of rotation would be established whereby any advantages one season might have over another would be equally distributed over the whole estate. How to prune, like everything else in the cultivation of tea, depends largely on circumstances. Here where wind is a serious drawback, I have found pruning down to 10, and 12 inches most successful; the bush

thus formed has certainly not the broad surface of one pruned at say 20 inches, but on the other hand, the former is far and away more compact than the latter, and is therefore not only better able to withstand wind but gives a much heavier yield per acre. The tea made from low pruning requires longer to attain its best than by the other system—small "couthiss" should be cut back to within an inch of the stem, else they will bud more shoots than they can develop.

PLUCKING.—I have tried leaving four, three and two full leaves on primary shoots, and find that the last is ample except in the case of shoots from the lower part of the bush when three leaves are not too many; on secondary and subsequent shoots, I leave only one leaf; while after the bush has become fully formed, an occasional plucking down to the abortive leaf is an advantage. If more than three leaves are left on primary shoots the chances are a large proportion of the eyes will never develop, and the bush runs up; the same argument applies to secondary and subsequent flushes if more than one leaf is left, the result being the formation of unnecessary wood which might otherwise have gone to the factory in the form of leaf. Owing to the "washy" nature of tea made during the first three or four months after pruning it is hardly worth while plucking other than fine during that time.

WITHERING.—Only where rolling power is abundant can tea be made to the best advantage. The conditions for the best possible "wither" are the minimum amount of moisture in the leaf, and the maximum amount of flexibility; usually this requires the absorbing of 40 per cent of the original moisture. Generally speaking, it requires 3 horsepower to manipulate a roll of 120 lb. of properly withered leaf. Where rolling power is deficient it is advisable to under-wither proportionally. If, as occasionally happens, the leaf becomes over-withered, I have found it an advantage to put only half the usual quantity of leaf into the roller, and thus materially increase the power available and preserve the quality of the tea by quickening the process of rolling, reducing friction and thereby temperature.

FIRING.—Teas allowed to retain from 5 to 7 per cent of moisture, keep better, have a better flavour and outturn, than if fully fired. The temperature should be about 240° Fahr. until oxidation has ceased, after which it should be reduced to about 200° Fahr. Where practicable, I should say sifting while firing would be an advantage.

[It will be well if our correspondents kindly give the name of district and approximate altitude from which they write.—Ed.]

TEA FOR LOCAL SALES AND AUSTRALIAN MARKET: GOOD ADVICE TO PLANTERS:

Colombo, 20th July 1889.

DEAR SIR,—Allow me to suggest through the medium of your columns, to planters who sell their teas in the local market that they pack more of their teas in *half-chests*, as chests are not suitable for the Australian trade, or at least only to a small extent.

I am sure, if the teas are suitable, that Australian buyers will pay a price which will much more than cover the extra expense of the smaller packages and one higher than the tea would realize in chests when only London buyers compete for the tea.

The classes of tea most wanted by Australian buyers are *leafy* broken pekoes, good, well made pekoes and useful pekoe souchongs, the thicker and more sappy the liquor the better. As to weights I would suggest 50 lb. net as the most suitable and that the teas be "factory bulked." Brokers would do well to print this in their catalogues as they used to do formerly, saving intending buyers the trouble of going round to the various godowns prior to the sale, a troublesome job when teas are lying out of Colombo,

to ascertain for themselves. If this information is not always available at the time the teas are printed, it could be given out in the room.

There is another point to which I wish to draw planters' attention, and that is the marking of the packages for local sale:—To avoid marking packages "London," as it is does not necessarily follow that the tea goes there. Certain teas came under my notice today which were marked "London" on two sides and on the other two with the estate name etc. As the tea is being shipped to quite another part of the world, it necessitated the word "London" being either obliterated or erased, which does not add to the neatness of the package. The following is all the estate marking necessary: anything additional is waste of ink, time and labour:—

(Chest) No—(left-hand corner)

(Estate) name (omitting the word "Estate")

(The first letters of the grade thus)

B. P. (for broken pekoe)

nett lbs.

and under the letters "B. P." the words "bulked" if it is so. Do not mark on more than one side of the package, say the end. When packages are covered with marking it is difficult to find a clear place to put a shipping mark.

Messrs. I. A. Rucker & Bencraft must be rather tired of writing so often on the subject of marking packages, but they like myself see that it is necessary, which is the only reason I have for again referring to the matter.

Apologizing for taking up so much of your valuable space for such, apparently, trivial matters, Yours faithfully,
F. F. STREET.

THE SCRAPING OF CINNAMON CHIPS.

Golua Pokuna, Negombo, 22nd July 1889.

DEAR SIR,—In my remarks at the opening of the meeting in cinnamon chips, I am made to say that the annual export of cassia chips from China is about 3,000,000 lb.; this should be 13,000,000 lb. Kindly please make this correction in your Overland issue.

I should have stated to the meeting that in a conversation with him in the hall Mr. Jacob de Mel, who had in his letter to me stipulated for permission to scrape chips for conversion into oil, in a very liberal and generous spirit withdrew that objection, and assured me that if he continued the proportion of cinnamon bark oil he would buy chips for the purpose in the local market. No doubt Mr. de Mel's brothers are of the same mind in this matter; and it is to be hoped that any who are holding aloof from this movement will be stimulated by this public-spirited example to come forward and join it.—Yours truly,

WILLIAM JARDINE.

HOW TO USE A HYGROMETER.

July 26th, 1889.

DEAR SIR,—Can you or any of your readers tell me how to use a hygrometer?—Yours truly, K.

[If the hygrometer your correspondent "K." refers to is of the usual type (dry—and wet-bulb thermometers) the following remarks will apply:—The instrument must be placed where direct sunshine or other disturbing sources of heat cannot affect it. The air must play freely around it, but it

must be sheltered from wind and rain. The wet-bulb must be covered with a single thickness of fine linen or muslin, which should be in contact with the greater part of the bulb, not gathered up into few more than necessary. The water glass must be filled with clear distilled or rain water. At old strands of darning cotton should be tied round the muslin at the neck of the bulb, and their ends should dip into the water in the glass. The bulbs will then be kept moist by the capillary action of the cotton wick and muslin. It should not be wet; if it is found that the water is supplied too freely, the number of threads in the wick must be reduced, or the water-glass lowered. If, on the other hand, the water does not rise sufficiently to keep the bulb constantly moist in the driest weather, the wick must be added to, and the water-vessel raised. The muslin and wick should be renewed before they get dirty, and should be boiled before use. The dry-bulb must be kept clean and dry. The temperature of the dry-bulb and the difference of temperature between the dry and wet bulbs are the arguments with which to enter the tables of "Relative Humidity" &c. which are always used in connection with this type of instrument.—A. E. W.]

TEA IN THE LUCKIMPORE DISTRICT: WONDERFUL RETURNS.—We call attention to the report of proceedings in connection with the Jokai (Luckimpore) Tea Company in another column. Mr. Berry White's estimates of the cost at which tea can be produced in this Luckimpore district, "the natural home of the tea plant" are astounding. If perfectly reliable, which we suppose they are, we suspect Ceylon must take a very secondary place after Luckimpore. But the district referred to is exceptional,—by far the most favoured scene of tea cultivation in India, perhaps in the world. In the large majority of the other Indian districts, the figures for production are quite double those adduced. If, as Mr. Berry White, with his well-known love for his neighbours, so magnanimously suggested Ceylon planters will have to supersede tea by other plants, a great many Indian planters will have to follow suit or shut up. If after all, some readers regard Mr. Berry White's utterances are somewhat gaseous, we can scarcely wonder.

PODOPHYLLIN IN THE HIMALAYAS.—The Lahore paper writes:—"Dr. George Watt, C.I.E., has made a discovery which seems likely to provide the hill tribes of the higher Himalaya with a lucrative trade, and to supply the medical profession with an abundance of podophyllin, a drug which, as many Anglo-Indians have good reason to know, is a valuable specific in disorders of the liver. Hitherto America has enjoyed a monopoly of the podophyllin plant (*podophyllum peltatum*), but the researches of Dr. Watt and the analysis by Dr. Hooper, Quinologist to the Madras Government, demonstrate that the Himalayan variety (*podophyllum Emodi*) yield three times as much of the valuable resin as the American root, and that it possesses the same medicinal properties. This valuable plant grows wild in the higher, rich and shady temperate forests from Sikkim to Simla, Kashmir, Hazara Tibet, the Kuram Valley and Afghanistan. It is fairly plentiful on the northern forest-clad slope of the familiar Shalai hill, seen from Simla; on the almost equally well-known Nagkanda hill, and in the Chumba State there are many mixed forests with their glades almost exclusively covered with this peony-rose like herb. In his notes on the subject Dr. Watt remarks that it is surprising that the natives of India, who have discovered so many drugs, should have failed to detect the properties of the podophyllum root."—*Pioneer*.

AN ENGLISH RUBY COMPANY FOR BURMA:
WHY NOT A LONDON GEM COMPANY
FOR CEYLON?—NO. VI.

SOME OBSERVATIONS ON SIR LEPEL GRIFFIN'S SPEECH AT THE GENERAL MEETING OF THE BURMA RUBY MINE COMPANY IN LONDON—MR. STREETER ON THE GEM MATRIX OF CEYLON.

It is not a little remarkable that, at the very time the *Ceylon Observer* was endeavouring to demonstrate that many of the more important advantages claimed for the Burma Ruby Mine Company by Mr. Streeter were either very much exaggerated or had no existence at all, the very same facts were being adduced at the statutory general meeting of the shareholders of the Company in London as justification of there being no ostensible results from their operations in Burma. Sir Lepel Griffin, who presided on that occasion, is a speaker who is in the habit of putting what he has to say before his hearers in lucid and forcible terms, as we must all acknowledge after reading his eloquent address at the Colonial Institute on the native Princes of India. On this occasion Sir Lepel Griffin had several things to tell the shareholders which by rights they should have been told six months previously—and which unpleasant in themselves—would be more unpalatable coming upon them as they did in the way of a surprise.

He had to tell them, and did so very plainly, precisely what the *Observer* told its readers, that the vaunted monopoly was no monopoly, that the pacificated Burma was not pacificated or likely to be for some time, and that the difficulties of communication were so immense that they had not as yet been overcome and no fixed date could safely be named for the machinery to reach the mines though it had been sent up early in the year to the station on the banks of the Irrawady. As regards the monopoly, so far as may be gathered from a brief report of his speech, one allusion only was made to it by the chairman, but that one was quite sufficient for the purpose. He said: "They would have to deal also with the difficulty of smuggling, owing to the rights of mining possessed by certain natives. He trusted however, with the help of Government, they would be able to make arrangements by which this would be overcome. These native miners were not allowed to use machinery or explosives." This inhibition we learn has only been recently imposed by the authorities, and in the present disturbed state of the country would be as difficult to enforce as an inhibition of dacoity, and being of little importance to Government it will not receive much of their attention. Here then, at last, we have an admission from headquarters that other natives, beside the Ruby Mine Company have mining rights of importance, and consequently that the Company has no monopoly. After what has been written previously on this point there is no necessity to enlarge upon it now, only let us hear no more of the monopoly in Burma which a Gemming Company in Ceylon could not obtain, and does not require.

Let us then turn to the "pacificated" state of Upper Burma:—"The most important of the difficulties before them—because the most difficult to overcome—and one which was entirely outside the operations of the Company, was the disturbed state of the province of Burma. He was however confident that the Government were acting with ability and energy, and that in a very short space of time—it might be months or a little longer—Burma would settle down into that state of order and peace which reigned in every other part of Her

Majesty's dominions. No doubt however so long as Upper Burma was ravaged by dacoits the operations of the Company would necessarily be exposed to some inconvenience and interruption." Precisely so. The measure of time coming next after months is commonly years, and we may very well read Sir Lepel Griffin's speech as running thus: "It might be months or it might be years" before the country attained a state of order and peace. Judging from the speeches by the highest authorities at the "Burma dinner" in London, a few days ago, those engaged in the work of pacification are by no means sanguine of success for a very lengthened term, as much as ten years from the date of annexation being mentioned as not improbable. This is indeed anything but a bright lookout for the Ruby Company, whose lease is only made out for a seven years' tenure. It is a matter of some significance that the Deputy Commissioner of the Ruby Mines District has lately been removed from his position for furnishing information to the press—or at any rate to interested parties in London. This has been done, it is stated in Burma papers, after a previous warning and promises made by the Commissioner to abstain from commenting upon the state of the district over which he had control. Sir Lepel Griffin must have found rather a difficulty in "prophesying smooth things" for the future, and barely succeeded in doing so with any degree of success. The other difficulty mentioned by the Chairman is the one on which we most strongly insisted some months ago, when discussing the comparative advantages of the Ruby Mine Company for Burma and a Gemming Company in Ceylon:—"The next matter of difficulty was the communications. The Burma mines were situated in the heart of a mountainous country, but the construction of a road to Mogok was being energetically proceeded with. Their Superintending Engineer, under date of May 20th, stated that it was hoped to get this road open within a couple of months, though the writer added—all would depend upon the amount of labour available. This question of the road was of supreme importance to the Company, for they could not get their machinery up to the mines without it." Here is another revelation of great importance. Expensive machinery sent out from Europe with a staff of European workmen, lying idle six months already, and likely to remain so for an indefinite period; the salaries running on all the while, as well as interest on the cost of the machinery, which in a climate like that of the Shan hills, cannot fail to deteriorate rapidly. The amount of labour available for this work mainly depends upon the state of the surrounding district. In its present disturbed condition labour cannot be obtained at all, or in very small quantity, working under military protection. From another source we learn that "a hill road now connects Thabeitkyin with Bernardmyo, the sanitarium and military post in the ruby mines district, a distance of sixty miles. Fifty miles of this road are laid out and bridged, and have long been opened to traffic. It is excavated from the hillside and cost the Government £30,000 which includes £5,000 spent by the military authorities on mule roads. Another branch road runs from Bernardmyo to Mogok, twenty miles in length, and before it is cut will cost about £10,000, exclusive of metalling." This was written on the spot on 1st June, and from its tenor we may gather that the earthwork had not then been completed and the cost of metalling was a matter beyond the writer's conjecture. From what we can learn from Sir Lepel Griffin's relation to the shareholders, we may feel pretty confident that a full year from the registration of the

Company on the 28th February last will have elapsed before any substantial commencement has been made by the employees of the Company in Burma, and the probabilities are that a much longer period will be required to shew any appreciable monetary result. All that the Chairman could say by way of encouragement was "The prospects of the Company are not only as good, but distinctly better than when the prospectus was issued. Nothing has occurred since then in any degree to shake my own confidence, or that of the Directors, in the future success of their exceedingly interesting enterprise, but the investors must have a little patience." In the position he held on the occasion, Sir Lepel Griffin could not well have said less, and these remarks are made only by way of showing under what immense difficulties the mining venture in Burma is being carried on, difficulties which mostly have no existence in Ceylon, and in such infinitesimal part as they are present are incomparably more easy to overcome than they would be in Burma.

There is another small matter of considerable interest in this connection to which attention should be drawn. It will, no doubt, be remembered that Mr. Streeter at his interview with the London Correspondent of the *Ceylon Observer* laid very great stress on the fact (if fact it is) that in Burma the Company had discovered the matrix in which the rubies were originally formed, and had secured it for themselves, having thereby an immense advantage over any Company working in Ceylon, who could only operate on the alluvial deposits in and near the rivers, where they would have difficulty in securing any but scattered deposits of inferior value, inferior, however, not from want of quality, but from want of quantity. But when exhibiting his specimens, at the recent meeting of the Royal Institute he made the following statement:—"At present little is doing at the mines, but much machinery, already on the ground, will be at work in October, and it is proposed that the river through Magök shall be first dredged, for there the rubies derived from wear and tear of the rocks must have been carried down for ages past; the natives have not found many at that place, but with the aid of machinery large finds are anticipated." This statement is not one which should be lightly regarded, as it has a most important bearing on our contention respecting Ceylon. Although the Company has secured a monopoly of the matrix from which vast numbers of valuable gems are to be extracted, they are not going to take advantage of this source of immense wealth to enable them to make a magnificent beginning—but are content to dredge the alluvial deposit from which Mr. Streeter (in one breath as regards Ceylon) says no great value can be taken, and in the next as regards Burma "large finds are anticipated." Which of these two antagonistic opinions is the one in which he really believes needs no expression on our part—it would have looked more disinterested however had he abstained from giving expression to that which is adverse to the proposition for a Gemming Company for Ceylon.

Still one point more calling for comment. Amongst the specimens exhibited at the Royal Institute were "samples of ruby in its matrix, which were therefore great curiosities and novelties. In one instance the matrix was of calospar associated with oxide of iron: *the stone had evidently travelled from a distance and was waterworn.*" From this, one would naturally imagine that the matrix was waterworn, and consequently had not been found *in situ* but in an alluvial deposit. If on the other hand the ruby itself was waterworn the so-called matrix was not a true one, possibly only a harder deposit

of what in Ceylon is called "*Ulan.*" This of course can only be decided by scientific men, and it will suffice to say that to an inquiry at Mandalay, as to what kind of a deposit it was in which the rubies were found and for which "crushing machinery" was necessary, the reply was to the effect that it was "merely a hard clay."

It would appear that little by little slowly but surely—proofs of what was advanced in the *Observer* of a month ago are gradually being drawn from the speeches of Mr. Streeter himself and Sir Lepel Griffin, and there can no longer exist any reasonable doubt that Ceylon offers an immensely superior field for Gemming operations to anything that can be found in Upper Burma at the present time, or will be for many years to come. There are many reasons which make it preferable for the Ceylon Gemming Enterprise that the Burma Company should be a successful one—and that handsome returns should accrue at an early date; for should it be otherwise, people who are not aware of the facts of the case will be apt to say: "Look at the Burma Company—with every possible advantage and with all the éclat of a magnificent commencement, it has done nothing as yet, what then can be expected of a similar venture in Ceylon?" If they could only be made acquainted with the truth of the case, the argument would be the other way.

PLUMBAGO AND GEM MINING IN CEYLON.

CAPITAL AND ENTERPRISE WANTED.

(FROM OUR MINING CORRESPONDENT.)

Sabaragamuwa, 22nd July 1889.

I send you a sample of what is to be found amongst the residue of washings out, as existing in the gemmers' baskets, which to the non-scientific explorer is a puzzle, and would afford a geological student any amount of study. The contents of the packet in my opinion afford ample proof of this island having undergone glacial action some time or other, and is sufficient to induce the Asiatic Society to undertake a strict geological survey of the country. In my travels I have come across the gem-yielding gravel, most of it of course far from being so rich as the present sample of washings represent, nearly all over the country, for some 30 miles round about Ratnapura, and in many places seams of black soft mica which if followed up leads to plumbago veins, which only requires a company with capital to work.* Plumbago you will find in this packet, which came out of the washings also, and is to be found in small quantities in most of the gem-pits opened. Some plumbago pits are worked at Rakwana and some near Nambapana yielding handsome profits to the owners, even with their narrowminded appliances and ancient method of working. Surely some of our Ceylon men at home could start a Plumbago and Gem Mining Company.

A VALUABLE PIT AND PRIMITIVE METHODS.

With regard to the former: I remember some years ago visiting a pit at Ragedara in Kurunegala district where a magnificent vein was being worked in the solid rock at a depth of about 200 ft., and all the material, stones, plumbago, water &c., was being handed up a ladder sort of arrangement from one man to another, from the bottom to the top, without one single modern mining piece of machinery. The vein was a magnificent one, about three

* Will our correspondent have another look at the "soft black mica," because some of the very finest plumbago is laminated after a fashion so closely resembling flakes of mica, that the natives believe in the transformation of mica into graphite!—Ed.

feet thick, the purest lump plumbago I ever saw being thrown from man to man all the way up this ladder and piled at the top. I remember remarking to the conductor of the works that they would soon be worked into a fix, as they were only blasting out the rock on each side of the plumbago seam about two feet. I could with my arms outstretched reach from side to side of the rocky opening where several men some on scaffolds were busy drilling holes for blasting. The conductor's reply to my query was that the vein grew thicker as they went deeper and it paid very well their stunted method of working which might not be the case if machinery were used, about which he could not vouch for being able to work satisfactorily. I then asked what profits were being realized by the proprietors, and he took me to his hut where he turned up his ledger, and much to my surprise, from actual figures showing the out-turn per month, from which I deducted R10 per ton for transport to Polgahawela railway station (the rate being paid at the time of my visit), I found that a

CLEAR PROFIT OF R5,000 PER MONTH

was being netted by the owners from the one pit, laid down at the railway station, and if I recollect rightly I included the royalty of R5 collected in those days at the mouth of the pits. I cannot say that all plumbago miners are so lucky as to find such a paying vein as the one mentioned, for it is—or at least was at that time, now some ten years ago,—the best mine in Ceylon, and I believe has long ago been closed owing to its unworkable depth.

FORTUNES FOR NATIVES IN PLUMBAGO.

Many natives who have engaged in plumbago mining have become immensely rich, and the few Europeans who have tried at it have failed for want of capital, and practical knowledge. The latter is just as essential as the former, and if not studied failure is sure to ensue, as many veins will not pay to work, as I know to my cost. Now plumbago is rising in price, and is likely to do so till its old price is reached viz R200 per ton, owing to the great and increasing demand for the mineral for lubricating purposes, and mixing with the grease used for railways. I think there is plenty of scope for European capital and enterprise at the venture in conjunction with gem mining.

SLOW CEYLON.

If any other country but Ceylon had been known to produce precious stones and plumbago for the past half-century in such paying quantities, over such a large area, no doubt many a company would have been at work ere now, and we should long ago have known what the mineral wealth of the island was. At present it is no mere conjecture as to plumbago mining paying where judiciously carried on: by reference to the de Mells, Fernaudos, and others who have been engaged at the enterprise for the past quarter of a century the truth of their prosperity or otherwise could be learnt.

WILL GEMMING PAY WITHOUT A MATRIX?

With reference to gemming also, the gem notary, Assen Marikar, Tambi Siñño and many others who have followed up the enterprise perseveringly could produce evidence of the profits to be realized from following the strata of gravel, settling the question of "Will it pay without a matrix?" With our

SPLENDID FACILITIES FOR TRANSPORT

by means of some of the finest roads in the world, comprising a network throughout the whole island, there need be no fears entertained by British capitalists, in that respect. Were a company to be floated, the machinery, etc., could be easily

sent free on board ship to any mines being worked in any part of Ceylon. There would be no such difficulties to contend with as are experienced in the Cape, Mexico, Australia, and elsewhere. For many years the Mexican miners had to transport their silver, provisions, etc. on the backs of mules to and from the coast by a mere rugged tract from an elevation of some thousands of feet. Provisions were paid for almost "a peso de plata" (by their weight in silver), contending with many other difficulties besides, till, after the State was proclaimed a republic in 1828, previous to which many of the mines were abandoned. Another civil war is required in Mexico to raise the price of our rupee.

["Wars and rumours of wars" are, unhappily, necessary to raise the value of plumbago; but we suspect that a civil war in Mexico would not greatly affect silver, while the mines of the United States and Australia produce the metal (demonetized over the larger portion of Europe) so abundantly. —Ed.]

WHAT IS SAID OF THE NEW CHINA TEAS, AND OF CEYLON TEAS, BY A LEADING LONDON BROKING HOUSE.

(From the London Times, July 5th.)

TEA.—From Messrs. Layton and Co.'s Circular.—China.—The China Mutual Shippers' steamer "Moyune" arrived in dock on Monday last, July 1st, and on Tuesday most of her cargo was placed upon the market, and in the course of the day 1,579 packages were offered at public sales, bringing from 5½d to 1s 5½d per lb. Privately there was no excitement, and only 1,500 packages were sold, the highest price obtained being 2s per lb. for a fine Ningchow; a fine chop of Kintuck brought 1s 10d, but there was very little demand for the lower grades, which form the bulk of the cargo. The appended figures show the continued declension of home trade in China tea, the deliveries showing a decrease of 2,500,000 lb, while Indian and Ceylon have increased about 3,000,000 lb. The stock of China tea is now fully 10,000,000 lb. below that at this date last year, which fact should infuse steadiness into the market. New-make Congou of new import has brought very disappointing rates, the low prices current for Ceylon teas affecting this class severely. The influence of the Produce Clearing-house has been somewhat felt in the demand for good common old season's Congou at 4½d to 5d, which are slightly steadier in consequence. Green Tea.—Although the present range of prices may be considered low, there is a fair demand for most descriptions, and a hardening tendency in current rates for all except No. 1 Moyune gunpowder. Scented.—Canton scented caper of new import has brought low prices, from 5½d. to 1s 0½d, and long-leaf Pekoe 6d to 9½d at public sale. Foochow kinds show no change. At our public auction this week the following have been the prices realized for China teas offered for unprotected sale:—New Moning, 5½d to 1s 5½d; new-make Congou 5½d to 7½d; old season's Congou, 4½d to 5d; Moyune gunpowder, 10½d to 1s 1½d; Moyune young Hyson, 5½d to 10½d; new Canton caper, 5½d to 6½d. Indian.—The deliveries continue to be highly favourable, and owing to light arrivals the stock is now reduced to comparatively narrow limits. Sales of new crop have recently shown increased firmness, really good teas bringing very satisfactory rates, while an improved demand prevails for the lower grades. Ceylon.—There can be no question that, generally speaking, all grades of Ceylon are now selling far below their comparative value with either India or China tea. This has been mainly brought about, not unnaturally, by the rapid increase of the production, which, although anticipated, has come as a surprise to the trade generally, who have been unable to deal with the large quantities offered. Another reason is the generally prevalent idea, which

is somewhat exaggerate^d, that all Ceylon tea rapidly deteriorates; no doubt this is true to a certain extent, but present rates, even allowing for this factor, are certainly too low, and we look for an important recovery shortly.

[It is surely time that this charge against Ceylon tea of special liability to "go off" should be decided, and if in favour of the allegation that the cause should be ascertained, so that the requisite remedy—slower firing? may be applied.—Ed.]

TANNIN IN TEA.

The *Pioneer* has the following deliverance on this subject:—

Some time ago we called the attention of Indian tea-growers and tea-merchants to a statement made by Sir Robert Hart, the Inspector-General of Maritime Customs in China, to the effect that Indian tea was much less wholesome than its Chinese rival. Sir Robert Hart gave no authority for his assertion; but in a recent report Mr. Allen, the British Vice-Consul at Hankow, adduces the results of a chemical experiment in proof of the same position. The test is said to have been made by Professor Dittmar, and to have shown 9.68 per cent tannin in Indian tea against 6.01 in Chinese. Also "after 20 minutes infusion of 100 grains of each there is present in the respective liquors 2.96 grains thein and 6.53 grains tannin in the Indian, and 3.37 grains thein and 3.86 grains tannin in Chinese tea." This last way of putting the matter is scarcely to the point, as no one wishes to infuse tea for 20 minutes and everyone knows that to make an infusion of equal strength less Indian tea is required than Chinese; but here is little doubt that reports like that of Mr. Allen's if allowed to go unchallenged, will hurt the prospects of Indian tea in the European market.

Our contemporary is quite right about the absurdity of giving results after 20 minutes' infusion. It may interest the *Pioneer* to learn that Ceylon high-grown teas have been analysed by Mr. John Hughes of Mark Lane with the following result:—

Moisture dried at 212° F.	...	7.30
Chlorophyl and oil	...	2.25
Soluble tannin	...	6.37
Other soluble organic matters	...	29.03
Suble mineral matters	...	2.50
Vegetable fibre and insoluble organic matters	...	49.62
Insoluble mineral matters	...	2.93
		100.00

A CORNER IN QUININE.

To the Editor of "The Financial News."

SIR,—Will you allow me to draw attention, through the medium of your influential paper to the very remarkable position of quinine?

Here are a few facts, which no doubt will be of interest to some of your numerous readers:—

Import of cinchona bark (from which quinine is made): October, 1885, to May, 1886, 10,900,000 lb. (price of quinine, 3s 6d per oz.); October, 1888, to May, 1889, 7,600,000 lb. (price of quinine, 1s per oz.), or a decrease of 3,300,000 lb. Export: First five months of 1886, 47,431 cwt.; against 54,265 cwt. for the first five months of 1889.

Thus we see a decrease in the imports and an increase in the exports; yet, in the face of this, quinine has dropped from 3s 6d to 1s per oz., instead of increasing or, at least maintaining its position. Why is this? Because bear sellers, who are almost exclusively German manufacturers, have been selling to an enormous extent for forward delivery; but when these deliveries became due, by offering a small quantity on the spot at a low rate, they have been able to buy back their own contracts at a considerable reduction on the price at which they sold. This has been going on for a considerable time, until now they have brought quinine to its present absurdly low quotation, viz., 1s per oz., at which price it

does not seem possible that it can pay; and this view is borne out by the fact that in some contracts made for July delivery, with the special stipulation that the quinine was to be delivered "direct from the works" within the previous three or four months, the goods have been tendered; but when the buyers demand proof of the recent delivery from the manufactory, they have, up to the present, been unable to obtain it.

The quinine sold for delivery in August next (apart from the normal consumption, which is continually increasing) is over a quarter of million ounces; so that if buyers will only demand delivery of the goods, instead of re-selling them at a loss to the very persons they bought them from, the bears would be entirely at their mercy.

Many people seem afraid of the present stock of cinchona in London; but on May 31st 1885, the stock was 76,500 packages against 65,700 on May 31st in the present year, thus showing another falling-off to the extent of over 10,000 packages; and it must be mentioned that a great deal of the present stock is absolute rubbish, the sale of which would not even realise the amount of the dock charges incurred upon it, without reckoning freight and the original cost of the goods.

Judging from these facts, it would seem that a capitalist with a moderate amount of capital—say, about £100,000—could entirely control the market, and send up the price of quinine 300 or 400 per cent, in a very short time, as the supply of cinchona is limited, and it requires from four to five years for new trees to arrive at maturity thus distinguishing it from mines and other undertakings, the production from which is mostly a matter of labour and money, any amount of which will not materially hasten the growth of a cinchona tree.—I am, sir, yours, &c. COMMON SENSE.

A CEYLON PLANTER IN MINCING LANE:

CEYLON TEAS IN MINCING LANE AND THE VICINITY—THE CRY FOR FLAVOUR AND QUALITY—A GOOD STORY—EFFECTS OF DRINKING "OOLONGS"—PLANTERS AND THEIR BROKERS—FALLING-OFF IN QUALITY MEANS FALLING-OFF IN PRICES—HOW TO AVOID IT: PRACTICAL ADVICE AND ILLUSTRATIONS—SHAKESPEARE APPLIED TO THE CEYLON PLANTER.

There can be no doubt it is good for us all sometimes "to see ourselves as others see us," and this outside view of the Ceylon tea planter can be had, I will not say enjoyed, on a visit to Mincing Lane, and the parts that do adjacent lie.

It would be "piper's news" to tell you that "flavour" and "quality" are all the cry in the city now, and though I think some of the acutest spirits have begun to grasp the idea that these characteristics cannot in many cases be imparted for reasons known to all of you, the cry does not diminish in its loudness nor is it likely to do so. Not but that there is a demand for bad teas, or what the tasters would describe as bad teas, but in the nature of things there will always be a supply equal to this demand. To explain the above I may say I was informed that in certain districts of the English Midlands and Scottish Highlands they would take nothing but thick, over-fermented teas; and in connection with this an amusing story was told me. On a certain estate in a favourite district the teas turned out were much inferior in liquor and valuation to those from the surrounding estates. They sold, nevertheless, very well; but after a time the manager, who was evidently not a believer in the old saying, "Let well alone," changed his mode of manufacture and turned out the same style of tea as his neighbours. This was at once followed by the buyers, who had hitherto taken these teas for special markets, transferring their affections elsewhere and by a fall in price. The moral

which the broker deduces from this is "Let every estate have its own characteristics, avoid uniformity." But it is only natural to suppose that in time the taste for bad teas will die out, and that the sounder and better our teas are the better prices they will command in the long run. One may here spare a pitying thought for the poor wretch who can complacently swallow a cup of "oolong" pure and simple. To what depths of depravity, mental and stomachic, must he have sunk!

But an entire coincidence of views between the planter who wishes to make his estate pay and the broker who wishes to sell good tea and get the good prices (for I give these credit of wishing that) cannot be looked for. I do think, however, this divergence is greater than it need be. And here I approach a somewhat delicate subject. It is not so much the quantity of Ceylon teas coming forward that is complained of, but the falling-off in quality. Now it may be heresy to say so, but I have come to the conclusion that from the broker's point of view they have distinctly fallen off. Be it admitted that as much hard work has been put into the last 20 million lb. exported as into any other equal quantity ever made, but hard work will not make good tea. Take a typical case such as the following which can be matched in every district in the island. A planter has 50 acres of tea ready to pluck. He puts up half-a-dozen chulas, sends 3 of his best coolies to a neighbour to learn to roll and fire, gets a fortnight's leave to learn something of plucking, and starts operations. May be he spoils a chest or two, but after a bit he turns out first-class teas and dispatches every month a small break, the prices of which are satisfactory to all concerned. All this time he has been in and out of his little factory all day long and often in the night. Every leaf has been well and evenly withered, and he has handled the trays of roll as Isaak Walton did his worms, "as if he loved them." He has now established a certain *standard* for his teas which he and his proprietor fondly hope will be maintained. A permanent factory is now put up, roller and drier bought, five times the amount of tea turned out every now and then double the amount of leaf is taken in which the sheds will hold, and what is the result? A decline of 4d a lb.

The planter is disappointed. "But," says he, "you can't expect to keep up fancy prices when you have to make 60,000 lb. in a little place like that." No, my friend, very likely not. But the broker has nothing to do with that. His knowledge of tea-making, unless he happens to have travelled in the East, is very much like that of agriculture possessed by Mark Twain when he edited a farmer's journal ("do not shake the turnips from the trees but send up a boy to pick them"). His business is to report on the teas, and he does so to this effect:—"These teas are wanting in point and have lost the delicate flavour which used to characterize shipments from this estate," and so on and so forth.

Now it seems to me that this sort of thing repeated on half the estates in the island will in itself account for the falling-off in teas so much talked about. That being so, the question arises "How are we to avoid it." Well, we cannot avoid it. But we can minimize it. How common it is to hear such remarks as the following in Ceylon: "I'm making the most awful muck just now." "The leaf was 6 inches deep all over the floor last night." "had to fire at 270 to work off the rolls," &c., &c. Very good. Any man whose leaf was 6 inches deep last night has driven a nail into our coffin. Not a harmless little taintack, look you, but a great big brass-headed nail.

The time must come—the time will come—when if we are to make a living at all, Ceylon tea must be a synonym for "good tea" and "sound tea," and tea made under the above conditions is not "good tea" and is not "sound tea." No one thinks of mixing his "tails" with his "first parchment": why then should he calmly ship home a break half of which he knows is utterly bad?

Yet such things have been done every day; and so long as these shipments brought an average which though not high still left a profit, it was perhaps too much to expect from human nature to resist the temptation. But that time is past and never will return. I cannot say "Be warned in time," for we have not been warned in time and now we have got to suffer it; but when pekoe souchong arrives in London as happened last week which is valued at 3d a lb., one begins to hope that the irresistible logic of facts will bring it home even to the poor creature who shipped this poison that it does not pay. Any higher argument would probably be thrown away on him. One can understand, too, the piteous tone of the broker who said to me "What *are* we to do with stuff like this?"

I have, of course, written broadly and generally, but when all is said and done it must occasionally happen that a batch is, for instance, over-fermented: what then should be done with it? The broker tells you "Go on over-fermenting, send us an over-fermented break, and the chances are it will find a buyer for some local market, but do not mix it with good tea and make the whole break without point."

Be that as it may, the point I want to bring out is that every man who deliberately takes in more leaf than he can turn into sound tea is driving a knife into the heart of the enterprise.

Enlarge your factory if you will (ample withering accommodation is probably more important than anything) but do *anything*, stop buying leaf, abandon your best fields, use your bad tea for fuel or packing cheroots, but don't, whatever you do, send it to Colombo:—

Good name in man or woman, dear my lord,
Is the immediate jewel of their souls.
Who steals my purse steals trash; 't is something, nothing,
'T was mine, 't is his, and has been slave to thousands;
But he that filches from me my good name
Robs me of that which not enriches him
And leaves me poor indeed.

THE ASSAM TEA COMPANY.

The CHAIRMAN, in moving the adoption of the report, said that the year 1888 began with the promise of success.

PRICES.—Large quantities of tea were sent home, which realised some of the best prices that had been obtained for Indian tea, showing that their tea had not lost its ancient record. But this bright state of things did not last, for though larger quantities of tea had been sent home, there was a falling off in price, that obtained being 11½d against 1s ¾d the previous year. In this, however, they were more fortunate than their neighbours, who had a drop of 2d to 3d per lb. The fall they had thus experienced was equal in total value to a dividend of 6 per cent.

NEW PLANTS.—Instead of patching up in order to repair this weakness, which it was felt would be short-sighted policy, they had planted out 1,150 acres of new ground and cleared 750 acres more of the land which belonged to them. It was costly work, but they had done it as thoroughly and economically as possible, and they hoped the result would be seen in improved quality and quantity of their tea, and ultimate benefit to the shareholders. They had also made changes in the management of their estates. Under the old system, the whole of their gardens were controlled by one general manager, and their teas

were brought from the different gardens in carts mixed all together, good and medium alike, and packed in chests and sent off to London. Now they were decentralising and splitting up the estates into divisions of about 1,000 acres, with a manager to each, and these were all grouped under the management of a Calcutta firm—Messrs. Kilburn & Co., who periodically sent practical men for the purpose of maintaining an efficient inspection of all the gardens. The packing of the tea of each garden was now done on the spot at the different stations where the tea was manufactured, and so they would be able to tell which were the most successful, both in cultivation and manufacture, and would be able to test the ability and success or otherwise of each of their managers.

Mr. MCSWENEY urged that, whilst their tea cost them nearly 10½d. per lb., other companies were able to do it much cheaper. Besides which, companies he could mention produced from 50 to 100 per cent more tea per acre than the Assam Company. He had found from reports that some companies were getting 560lb. of tea per acre, against their 304 lb.

Mr. BULLOCK EXPLAINS.—Mr. Bullock, in the course of a lengthy and detailed speech, pointed out to the previous speaker that, whilst the price of the teas of the Assam Company had only fallen 1½d per lb., other companies' produce had fallen 2½d and 2 3-16d, so that, as compared with such, their company stood in a very favourable position. The fact was the unprecedentedly low price of tea was the cause of all their troubles at present. The improvements which had been made in the quality of their tea, if judged by the prices obtained in previous years, was about 2d per lb., which on their outturn would represent £14,000; then the directors had had to pay £2,000 more for freight, which could not be helped, whilst they had spent £5,000 on extensions. Therefore, he thought, looking at these facts, they would see that had they been in the same position as last year in these matters they would have paid a dividend of 22½ per cent.—*Home and Colonial Mail*, July 5th.

FIG CULTURE IN CEYLON.

The following interesting information from the *Treasury of Botany* is worth reprinting at this time when attention has been directed to fig culture in Ceylon:—

The Fig of our gardens is the *F. Carica* of botanists. The name *Ficus*, applied to this very anciently known fruit, is most probably derived from Feg, its Hebrew name; that of *Carica* is from Caria in Asia Minor, where fine varieties of it have long existed. According to various authors, it is a native of Western Asia, Northern Africa, and the south of Europe, including Greece and Italy. It is certainly indigenous to Asia Minor; but it may have been thence introduced and naturalised in the islands of the Mediterranean, and the countries near its shores, both in Europe and Africa.

The Fig is a deciduous tree, fifteen to twenty or even thirty feet high in favourable climates. The alternate leaves are cordate, more or less deeply three to five lobed, and rough. The fruit is generally shortly turbinate, but some varieties are of an elongated pyriform shape; the skin soft, with shallow longitudinal furrows; the colour yellowish-white, greenish-brown, purplish-brown, violet, or dark purple. It consists of a hollow fleshy receptacle with an orifice in the top, which is surrounded and nearly closed by a number of imbricated scales—as many as 200, according to Duhamel. The flowers, unlike those of most fruit-trees, make no outward appearance, but are concealed within the fig on its internal surface; they are male and female, the former situated near the orifice, the latter in that part of the concavity next the stalk. On cutting open a fig, when it has attained little more than one-third its size, the flowers will be seen in full development, and, provided the stamens are perfect, fertilisation takes place at that stage of growth. But it often happens that the stamens are imperfect, and no seeds

are formed; nevertheless the fruit swells and ripens.

Under favourable circumstances, a fruit or two is formed along the shoots at the base of almost every leaf. Of these the quantity that sometimes attains maturity is enormous; but frequently, from vicissitudes of cold in some climates and heat in others, much of the fruit drops prematurely. It may not do so at the time when dryness prevails, but at some future period when moisture is sufficiently abundant: in fact, the injury caused by drought to this fruit becomes most apparent after moisture has started the tree into vigorous growth, and hence the true but remote cause of failure in the crop is apt to be overlooked. And if this be sometimes the case now, it was much more likely to be generally so in former times, when there was among cultivators but little intelligence as regards tracing effects to their causes. Accordingly, to prevent the fruit of the Fig tree from dropping prematurely, and to hasten its ripening, the process of *caprifigation* was resorted to. This consisted in placing the fruit of a wild sort, called the Caprifig, among the cultivated ones. An insect of the gnat family infests the former, which it leaves to attack the latter, entering to the interior of the fruit by the orifice. It is a very ancient practice for it is mentioned by the earliest Greek writers of natural history, and is even minutely described by Theophrastus. It appears to have originated in Greece. Pliny remarks that it was only used in the island of the Archipelago; that in his time, it was entirely unknown to the Italians; and that there was no tradition of its ever having been introduced to Syria or Palestine. Its utility was doubted by some authors, and among others by the celebrated Duhamel. He thought it questionable whether by caprifigation the maturity of the fruit was hastened, except in the same way as apples and pears are when attacked by the grub. Professor Gasparini, in an essay written for the Royal Academy of Sciences of Naples details a number of experiments which he had made, and repeated in different years. Their results led to the conclusion that caprifigation is useless for the setting and ripening of the fruit, and instead of making the figs remain on the tree, it either causes or facilitates their fall, especially when the insect has penetrated into the inside, and produced decay by its own death. According to Gasparini, the practice of caprifigation ought to be abolished, as it entails expense, and deteriorates the flavour of the figs. The French naturalist, Oliver, says it is being abandoned in some islands of the Archipelago where it was formerly practised, but in which excellent figs are still produced. We have thought it necessary to briefly notice the operation, as so much has been written with regard to its presumed advantageous effects; but from what has been stated, it will be seen that, according to the investigations of modern science, it is proved to be not only unnecessary, but positively injurious.

Figs have been used in the east as an article of food from time immemorial. They were amongst the fruits brought back from Canaan by the Israelites sent by Moses to report on the productions of that land. We read of a present having been made to David of 200 cakes of figs. They were probably used chiefly in the dried state. The drying is easily effected in a warm climate by exposure to the sun's rays, in the same way as those grapes are dried, which are called from that circumstance raisins of the sun. Like the grape, the substance of the fig abounds in what is termed grape sugar. In drying, some of this exudes and forms that soft white powder which we see on the imported dried figs. They are thus preserved in their own sugar, and rendered fit for storing up as an article of food.

Figs were considered of such necessity by the Athenians that their exportation from Africa was prohibited. Those who informed against persons violating this law were called 'Sycophantai,' from two Greek words signifying the discoverers of figs. These informers appear to have been especially disliked, for their name gave rise to the term sycophant, used for designing liars and impostors generally, as well as flatterers.

The Figs of Athens were celebrated for their exquisite flavour; and Xerxes was induced by them to undertake the conquest of Attica. The African figs were also much admired at Rome, although Pliny says, 'it is not long since they began to grow figs in Africa.' Cato, in order to stimulate the Roman senators to declare war against Carthage, showed them a fig brought from thence. It was fresh and in good condition, and all agreed that it must have been quite recently pulled from the tree. 'Yes,' said Cato, 'It is not yet three days since this fig was gathered at Carthage; see by it how near to the walls of the city we have a mortal enemy.' This argument determined the Senate to commence the third Punic war, the result of which was that Carthage, the rival of Rome, was utterly destroyed.

Only six varieties of Figs were known in Italy in the time of Cato. Others were introduced from Negropont and Scio, according to Pliny, who gives a catalogue of thirty sorts. The fig may have been introduced into Britain, along with the vine, by the Romans, or subsequently by the monks. But if it had, it seems to have disappeared till brought from Italy by Cardinal Pole, either when he returned from that country in 1525, or after his second residence abroad in 1548. In either case the identical trees which he brought, and which were planted in the garden of the Archiepiscopal Palace at Lambeth, have certainly existed for more than 300 years. This proves that the fig lives to a great age, even under less favourable circumstances than it enjoys in its native country. Another tree, brought from Aleppo by Dr. Pocock, was planted in the garden of one of the colleges at Oxford in 1648. Having been injured by fire in 1809, the old trunk decayed and was removed, but fresh shoots sprang up, some of which in 1819 were twenty-one feet high. In this country a chalk subsoil, and a climate like that near the south coast, appear to suit the fig best. There the trees grow and bear as standards. They are liable, however, to be killed to the ground in winters of excessive severity; but they spring up afresh from the roots. There was an orchard, not exceeding three-quarters of an acre, at Tarring, near Worthing, in Sussex, containing 100 standard fig-trees. About 100 dozen of ripe figs were usually gathered daily from these trees during August, September, and October. By selecting similarly favourable spots, it may be fairly concluded that this country could supply itself with abundance of fresh figs. As for dry ones, they are obtained in large quantities from Turkey, the Mediterranean, and other countries; but the supply for centuries back has chiefly been from Turkey. The import has been as much as 1,000 tons a year; and now that the duty is taken off, the quantity imported will doubtless be much greater. The wood of the Fig is soft and spongy; and as it can in consequence be easily charged with oil and emery, it is used in some countries by locksmiths and armourers for polishing. [R. T.]

From an American Horticultural Dictionary—Johnson's Gardener's Dictionary—we quote as follows some very practical information:—

Fig. *Ficus Carica*.

Varieties.—For forcing, we recommend the *Brown Turkey*, or *Lee's Perpetual*, *Pregussata*, and *White Marseilles*. The *Neri* is also well spoken of. To plant out-doors, the *Brunswick*, *Brown Turkey*, *Brown Ischia*, *Black Ischia*, and *Pregussata*.

Propagation.—The fig roots so firmly by *cuttings*, that few resort to any other mode. They propagate, however, as freely by *layers*. Some persons, also, have raised them from *seed*, but it does not appear that they are valuable, though new kinds have been originated by such means. *Cuttings* of ripe wood, about three or four inches long, planted in pots in January or February, and plunged in any ordinary bottom-heat, will make very nice plants during the same summer. Those for forcing in pots or boxes must be potted off when rooted, and again plunged in bottom warmth, and the highest course of culture pursued, shifting them when necessary. Those who plant on the open walls should do so in the middle of March;

and if the plants are from pots, the roots must be uncoiled and spread nicely out. Many persons who have established trees merely take *suckers* away from them; such only need fastening in the soil, and, it may be, a shading when they begin to grow.

Soil.—The fig will thrive in almost any ordinary garden-soil, but it is said to prefer a chalky loam. When planted against walls out of doors, care must be taken not to make the soil rich, for invincible grossness would be the consequence. A plain "maiden" soil is quite good enough for general purposes.

Culture in Growing Period.—Out-door culture consists in an early disbudding of all superfluous shoots; this is performed when the young shoots are about three inches long, reserving all those which are short-jointed and compact-looking. Care must be taken to reserve shoots for blank places. This disbudding is generally performed at twice or thrice during the season; for waste and watery-looking spray will continue to spring up until August, especially in moist summers, and when the plants are gross. Such disbudding should be carried out until almost every leaf of the future year's bearing-wood obtains a free exposure to sunshine, say by the middle of August. About the end of this month it is accounted good practice to pinch the ends of all growing shoots, or rather to squeeze them with the thumb and finger. Nothing more is needed as summer culture, except a timely training of all reserved shoots, in order to obtain all the sunlight possible.

Culture in Rest Period.—This merely consists in protection from frost, and in pruning. Towards the beginning of December, some protection ought to be given, as mats, straw, fern fronds, or spruce boughs. Before closing them, or, indeed, at the end of October, every fig which has become as large as a horse-bean, should be pulled away, for such rob the trees, and are sure to perish. The trees must be uncovered again in the end of February, if matted, otherwise such materials as fern or straw may remain on a little longer; the spruce, until *pruning* time. The latter operation should not be performed until the young buds are beginning to swell, when wood of a proper character may be distinguished readily from that which is useless. All the latter must be cut away, unless required for blank spaces; but if summer disbudding has been properly performed, there will be little for the pruner to do. After this, they must be duly trained.

Forcing.—Some build house for the fig, but most prefer growing them in tubs or large pots. The general principles of forcing them so closely resemble those for the vine, that it will be needless to go into details. As to general temperature, although they will bear much heat, yet most cultivators agree that one intermediate between the peach-house and the forcing vinery is the most congenial. It requires, however, a little more excitement to bring the fig into leaf than the peach. Under good house culture it will produce two satisfactory crops in one year. A first crop may be obtained as early as May, and after a couple of months or so, the second will commence ripening; the latter being those on the wood of the current season. The first crop, or the embryo fruit of the previous year, is very apt to fall prematurely, and much care is necessary. Regular waterings the moment they are dry, and an avoidance of atmospheric extremes are the best preventives. Most good cultivators make a point of pinching the ends of the young shoot when about six or eight eyes or buds in length; this soon causes the fruit to form in the axils of the leaves. Frequent syringings should be practised in the growing season; and at rest they should never be subjected to a lower temperature than 40°. Under all circumstances, the fig delights in a soil somewhat moist: a neglect of watering when necessary, even for a day, may cause them to cast their fruit.

Fruit.—Its use is almost entirely confined to the ripe state, as dessert; as for keeping, if such is attempted, it must be on the retarding system, by partial shade, and a lowering of temperature just before ripening.

Insects.—The *Red Spider* and the *Brown Scale* alone cause any alarm to Fig cultivators. The spider must be combated by the syringe, by an occasional dusting

of sulphur, and by dressing the shoots all over, before commencing forcing, with soap water and sulphur; three ounces of soft soap to a gallon of warm water, well beat up, adding four handfuls of sulphur, will make a mixture, which, brushed into every crevice, will extirpate both scale and spider. Sulphur, however should be used on the pipes during the growing season.

In Sicily, we see from a paper in the *Tropical Agriculturist* of January 1885, the fig is propagated from the suckers that spring up from the roots, cuttings from the tree being also used.

CEMENT CONCRETE TAPER PIPE SLUICES.

Mr. A. Murray, Provincial Assistant, P. W. D., has designed for the North-Central Province village tanks, cement concrete pipes, which are likely to afford an enormous saving to Government, as these sluices will cost about 1-30th of the iron pipe sluices hitherto put in. Mr. Murray's invention is the application of cement concrete to the manufacture of taper pipes and the design of a junction block to secure an efficient union between the vertical and horizontal sections. The whole arrangement is so simple that any villager can put in his own sluice, and all perishable material such as iron &c. is entirely done away with. The regulation of water supply is effected by insertion or removal of the pipes forming the vertical section as the water rises or abates. Messrs. Nock and T. C. Owen (both of whom were lately in the N.-C. Province) saw three of these sluices in full working order and were favourably impressed with them. The main features of the design are simplicity, cheapness and portability. Several have been fixed in position, *without the aid of skilled labour*, and are working admirably. Instead of sluicing 30 village tanks per annum the P. W. D. will now be able to sluice 300 and at 1-30th the cost per tank! This application to agriculture of a substance so valuable in structural operations is likely to produce results little short of a revolution in the rice-growing industry.

PLANTING IN NORTHERN QUEENSLAND.

[BY A WANDERING CEYLON PLANTER.]

After some eight or nine years of wandering in the Australasian colonies I write you as if writing "to the auto house at home," but first find enclosed order to forward me the *Tropical Agriculturist*. Since coming down here I have had rather a rough wandering time through the interior as also on the coast, east and west, and have been employed at any or all undertakings that came in the way, and the other week only I came here on a six months' engagement, (having travelled overland on horseback some seven hundred miles to take a six months' engagement,) just to get my hand and heart into coffee, cacao, &c., to which the proprietors are to give a full and faithful trial. So you will see I am ino propagating in all its stages, even my pet work from leaves, if I can get nothing better. I wrote my last employers in Ceylon to see if they could assist me to have some seeds forwarded (for my employers) as also get information as to charges. If I am successful, no doubt, you will hear from me now and again. I wish we had Ceylon people to get on with here. Australia would be another country from what it is.

This "Breton" is a fine estate of over 1,000 acres of dense jungle, impassable without a scrub knife for prickly creeping vines, which small animals cannot get through. There are also very fine timber trees of hard woods and cedar, and as yet there are only about 40 acres in cultivation with orange, lime, lemon, custardapple, soursop, pineapple, guava, peach, plums (of sorts); a native plum about the size of a

large Sinhalese fowl's egg, and of a deep plum colour called *Davidsonii* and a jasmine plum of very fine flavour; there are also native cherry, the branches weighed to the ground with crop. Mangoes grow very fine and rapidly in the jungles; bananas reach some 60 feet high, the Cavendish variety we cultivate only. There are several other things, ginger, arrowroot, tobacco, maize, &c., &c., but prices are so low that they deem fruit cultivation for the markets do not pay. Our labour is of a very poor sort, a handful of Kanakas and about 60 natives; the latter only get their food and now and then; clothes as they are required; they are untrained, untamed and quite wild cannibals at the best; but, as far as I have seen of them, they have been quiet, peaceable, but not industrious. Yet I would believe in course of time the children will become more tractable as civilization goes on. If any of these native fruits you have not got let me know and I would forward you a small parcel by the B. I. S. N. Company's steamer for you. Do you know, if there could be got through the agents, that these steamers would bring a case of cuttings, and germinated seeds, as deck cargo or keep them so they could get plenty of air? I brought on horseback two sacks of such for over three weeks and through a dry time, they were Bamba's Malay apple, cashewnut and a lot of other things, and after their long perishing they have rooted and growing vigorously. If they would bring them I would send an order and cash with instructions how they should be packed.

PEASANT PROPRIETORSHIP IN BRITTANY—The British Consul at Brest, in his last report, refers to the condition of the Breton peasant proprietor, and says that although he has a great natural aptitude for tilling the soil he labours under considerable disadvantages. As a rule, he cannot furnish himself with the proper plant, cattle, and implements for agriculture and, above all, bear the expense of draining. Nearly all the land cultivated by the peasant proprietor is worked with the spade, and the fear of losing, or even risking, the slender profit he is able to make by his severe labours effectually prevents any enterprise and engenders a spirit of avarice difficult to describe. The peasantry apparently live in a condition of squalor, happily unknown to the English agricultural labourer. Thanks, however, to their extraordinary parsimony, it is perhaps doubtful if they are actually as poor as they seem; but their pale and troubled faces and bent forms, even in early life, show how badly they are fed, whether they can afford comfort or not. In Brittany, certainly, under the peasant proprietorship system, the land is not properly worked and much goes out of cultivation. It is the custom to raise immense banks as hedges between their little plots, to grow scrub oak on. These banks, with their huge crest of scrub, shade the land to a great distance on each side, and from the resulting damp little or nil grow under them. The object is to obtain the firewood, which is of very slow growth, and the peasant in thus trying to get too much out of his plot, is half-starved, whilst half-killing himself with labour. Many other instances could be presented of the same shortsightedness in squeezing the land. Men and women indiscriminately perform the work of the agricultural animals they cannot afford to buy, with the usual consequent evils to health. It is no uncommon sight to see women working with the flail for hours, a labour so severe that it often breaks down the men.—*London Times*.

[There are two principles to be kept in view if the most is to be made of the land. Let it be the indefeasible property of the cultivator, but let that cultivator possess a sufficient area for the employment of capital, which he ought to possess to some extent, and labour. Peasant proprietorship of small holdings sounds well, but the results, even where, as in France, the utmost industry and thrift are exercised, are the reverse of satisfactory; industry degenerating into depressant slavery, and thrift passing into sordid poverty and blighted existence. In this as in other matters the co-operation of capital and labour are required to bring out the best results.—ED.]

GEMMING: CONSTITUENTS OF THE GRAVEL OF THE SABARAGAMUWA GEM REGION.

The correspondent who has supplied us, for the information of our readers, with so much valuable and interesting information respecting the gem formations in and around Ratnapura, sent us recently a specimen of the gravel in which, when the alluvial soil is washed away, the gems, mainly forms of corundum, are found. Our correspondent hazarded the opinion that the appearance of the detritus afforded a proof of former glacial action in Ceylon. This is not so certain as that the water-worn appearance of the pebbles and fragments indicate long-continued and very violent diluvial action,—action which, with the slower operation of a moist, hot atmosphere, seems to have reduced rock matrices to the level of alluvium. It would appear to be certain that more success is likely to attend deep diggings in alluvial matter, than any search (hitherto fruitless), in the still disintegrated rock formations, from the breaking-up of which Tennent, following Gygax, had such sanguine expectations. Having divided the gravel sent to us into portions and picked out specimens which seemed to us the most promising, we submitted the whole, with such guesses as we were able to make, to so competent an authority as Mr. George Armitage. With this gentleman's aid we are able to indicate the main mineral constituents of the gem gravel:—The larger fragments are, as might be anticipated, quartz, intermingled with bits of graphite and of the ubiquitous garnet, splendid specimens of which (in a mineralogical sense,) were found, with equally fine but treacherously slippery masses of mica, in the interior rocks of the Blackwater railway slip. In more or less advanced stages of decomposition, garnets pervade large portions of the prevailing gneiss. But the Ceylon garnets have never been mistaken for rubies, as were those of South Australia some time ago.—The smaller fragments of the gravel, out of which we had picked specimens, which were more or less gem-like in their crystallization, consist of quartz, garnets, spinel, &c. Fragments more or less lustrous and of a reddish to dark tinge, are pronounced to be spinels. Some of these are pretty, but of no intrinsic value. They bear no resemblance to the blue spinel sapphires, so common in some of our crystalline lime formations.—Small, black, hard fragments, which, when broken, show the lustre of graphite, but have nothing of the soft greasiness of plumbago, turn out to be the very common mineral, menaccanite, or titaniferous iron.—One dark stone, which looked promising and which we fancy would look well if polished, turns out to be a form of spinel known as ceylonite, the constituents of which are iron and magnesia.—The only specimen of sapphire in the gravel is a bit of white sapphire, the lustre of which is very pure. It is probable that any pieces of blue sapphire which may have occurred, were removed from the gravel. What we at first took for a fragment of blue sapphire, when examined by artificial light, turns out to be aquamarine, of which very large and pure specimens have been found in Ceylon, notably a fine specimen in the possession of Capt. Bayley. Our specimen is faintly coloured and badly crystallized. A very pretty conglomeration of lustrous facets, turns out to be mica, a mineral which can assume numerous forms and colours, plentiful as it is in our rocks. A dark, water-worn specimen with a resinous lustre, turns out to be opaque tourmaline, one of the most common pseudo-gems found in Ceylon diggings. A bit of rock-crystal is very easily distinguished from the specimen of

white sapphire, but to the uninitiated it would be very difficult indeed to distinguish a specimen which is pronounced by our authority to be the form of corundum known as the oriental amethyst, from a piece of garnet which is of a more solid structure than the ordinary form of, apparently, a number of crystals conglomerated.

It is unfortunate that the gem gravel contains no specimen, at least no appreciable specimen, of the blue sapphire for which Ceylon is so famous. As for ruby, that is now too rare in the ordinary diggings to be expected. But the list of minerals in the gem-gravel is pretty extensive, as will be obvious when we recapitulate them, thus:—quartz; rock crystal; white sapphire; oriental amethyst; Ceylonite, and other spinels; garnet; aquamarine; menaccanite; tourmaline; mica; graphite; with other mineral forms not identified.

What is desiderated in Ceylon as in other countries showing appreciable mineral wealth on the surface, is deep digging, and systematic search founded on scientific knowledge of the principles on which earths crystallize and ores aggregate. Deep and thorough mining may reveal not only a wealth of gems hitherto unthought of, but also gold and other metals in appreciable and paying quantities.

THE ALLEGED COCONUT LEAF DISEASE

(Communicated.)

Whether "B." in the local "Examiner" takes too serious a view of this matter or not, is a question to be decided by the scientists. The Government have done what lay in their power by appointing Mr. Drieberg to investigate and report upon the disease, and he with the means at his disposal has given his opinion. If, as is reported he has sent affected leaves to competent authorities for examination and report, I think the best plan is for us to wait till these reports are received and made public, which, no doubt, they will be in due time. "B." is entitled to his opinion as we all are to ours; and as his intentions are good and praiseworthy, he ought not to be blamed though in his excess of zeal for the public good he may have over-estimated the supposed danger. It is well that there are amongst us some wakeful and observant watchmen, for I am afraid too many of us are apt to slumber at our posts. "B." 's letters have no doubt disquieted the minds of many coconut owners, and therefore the sooner we have an authoritative verdict upon this question the better for us all. As for myself I do not think it serious, and indeed I am inclined to question if there is anything in the real nature of *disease* at all! "B." states that the disease is spreading, and it must be so in his locality. In this neighbourhood at any rate there is no spotting and dying of the tender fronds, and as for the blotching of the more mature leaves that is only natural in the process of decay; that this is any worse now than in former years I do not believe. Attention having been drawn to the matter more notice is taken of it, and one is apt to think that here and there perhaps a few trees look as if they had more decaying leaves than naturally they should have; but can any one say that this has not always existed, and not hitherto been looked upon as anything unusual? That a fungus has been discovered upon coconut leaves is nothing to be alarmed at, for what plant is there that is not the host of some parasite, vegetable or insect? When scientists distinctly tell us that our coconut trees are the prey of a fungus, which attacks the *green* fronds and, like the coffee leaf fungus, seeks the

life blood of its host, then, and not till then may we have cause for uneasiness. Why anticipate evil, an evil that may not exist, and which I trust may never come. Between Mr. Potter and Mr. Marshall Ward, and Mr. Drieberg's scientific friends, surely we shall not be kept much longer in doubt. J.

TEA AT HOME: WEIGHING, BULKING, BLENDING, AND SELLING:

The "average net weight" question is very much to the fore in Mincing Lane. One or two invoices offered this week were factory bulked teas, with average net weights. These failed to change hands in the sale room; possibly owing to their poor quality as much as to the fact that the leading dealers had agreed not to buy average net teas; the parcels referred to, sold to dealers after the auction, being purchased by brokers for clients who had not signed the circular against average net weight. It was announced from the box that all claims for short weight would be met in a reasonable spirit.

It will be very inconvenient, if not quite impossible, in these days to bulk and tare all the Indian and Ceylon teas. The trade is too large, and there would be too much delay, causing a block at the warehouses for want of space in which to conduct the operation. If the large importers are firm on the point we do not see how the opponents of factory bulking are to have their own way.

One important meeting, representative of the Indian and Ceylon planting interest, has been held on the subject. At this meeting the opinion was expressed that the action of the London Wholesale Tea Dealers' Association in declining point blank to buy any teas from India and Ceylon, unless weighed gross and tare, would put an end to bulking at the factory, and thus prove very prejudicial to the interest of planters. The plan proposed by the Dealers' Association simply means that each package must be turned out, the lead lining torn, and the tea, after exposure, repacked again anyhow. This retrograde proposal was much deprecated by all present, and a small but competent committee, consisting of three Indian and three Ceylon tea importers, was nominated to meet a similar number of representatives from the dealers. The latter, however, declined to reopen the question, and there the matter stands. Meantime, the committee are considering the next move. It is most unfortunate that, owing to the carelessness of a few, a system which offers great advantages, at any rate to planters and brokers, should fall into permanent disfavour with the traders at home. Now that the dealers have made a practical protest against careless bulking they might give the plan a further trial, and planters would see the necessity for carrying out the bulking with care.

We are not without hope that the difference between importers and dealers on the subject of factory bulking will yet be adjusted to the satisfaction of all concerned.

In their circular of yesterday's date, Messrs. Wm. Jas. and Hy. Thompson, commenting on the bulking question, say:—The question of the method of weighing tea—Ceylon as well as Indian—has reached the point at which a large number or the London dealers agree in declining to bid for teas weighed net. They ask either for each package to be weighed gross and an average tare taken by the Customs, where the packages are of sufficiently uniform tare, or, failing that, for separate weight and tare of each chest to be taken, as was the rule before the net weight system was introduced. It is so difficult to ensure an even delivery of tea in a break turned out for taring and re-packed, that re-bulking is often necessary, although before the taring the tea was even enough; and, when this is the case, the great care expended in bulking at the factory proves to be labour lost. If it is found necessary to revert to the system of London bulking and separate weights to the rule—retrograde as the movement seems to be economy of time

and labour at the factory, we must hope, will be some compensation for the extra expense of working here, and for the extra loss to the seller, over and above the 1lb. draft, which the old method of taking the weight entails. There is also the advantage of being able to put several invoices together here, provided they come by the same steamer and so to make large breaks of uniform quality—a matter of the first importance, for the trade has now attained dimensions which make large breaks an absolute necessity.

The subject of blending tea in bond has attracted some attention of late. A movement has been set on foot with the object of obtaining the right of blending tea in a bonded warehouse which is intended for home consumption. In reply to a question put recently to the Secretary of the Treasury in the House of Commons, Mr. Jackson replied to the effect that the Treasury had declined to sanction any arrangement by which tea required for use might be blended in bond, on the grounds that it would entail a large increase in the cost of the superintendence involved, and, moreover, there had been no general or unanimous opinion expressed by tea merchants in London or the country that the privilege, if granted, would be so advantageous as to warrant any considerable expenditure.

The Mazawattee tea case has been decided in favour of the plaintiffs. It was an action on behalf of the plaintiffs, Messrs. Densham & Sons, Eastcheap Buildings, Eastcheap, London, E. O., to restrain the defendants, Messrs. Doble, McCabe & Co., carrying on business under the style or firm of the Mallawattee Ceylon Tea Company, or any other style only colourably differing from the style or firm of the Mazawattee Ceylon Tea Company, under which name the plaintiffs carry on business. Mr. Justice North, in delivering judgment, said there was no doubt but that the defendants had selected a combination of words or parts of words with a view to obtaining the benefit of advertisements which were issued largely by the plaintiffs, while the defendants themselves did not advertise at all. The defendants had not only proceeded to copy the plaintiff's fancy name which as he had pointed out was one invented for this particular business, but they had proceeded to copy the plaintiff's labels with a view of getting as much of the plaintiffs trade as they could. Then the question remained whether the matter could be carried further, and it could be said there was a likelihood of the public being deceived. In the present case, as he read the evidence, actual deception had taken place, and he came to the conclusion that what had been done had been done deliberately by the defendants with a view of getting the benefit of the plaintiffs' business. The result was that he came to the conclusion that the plaintiffs were entitled to relief on the ground that the defendants had colourably imitated the plaintiffs' trade mark. There must therefore be an injunction to restrain the defendants from carrying on their business under the name of the Mallawattee Ceylon Tea Company, and in fact the injunction must go in terms of the notice of motion. Of course the defendants must pay the costs.

Messrs. Whitewright and Brown, wholesale tea dealers, trading also as the Ceylon Tea Company and the Indian Tea Company, whose failure has been much discussed in the Lane, passed their examination in bankruptcy on Tuesday.—*H. & C. Mail*, July 19th.

CEYLON AND THE GERMAN MUSEUMS.

AN INTERESTING ENTOMOLOGICAL TOUR.

That Ceylon offers a wide field for Naturalists is well known; but few insect-hunters who have visited our shores have made such an extensive collection during their stay here as has Herr Frühstorfer, a young German Naturalist from Berlin, who came to the island at the latter end of March, and who has now finished his tour. We mentioned when he arrived here, that he had great expectations of securing interesting insects; and it is very satisfactory to know that those expectations have been fulfilled. Leaving Colombo a

the beginning of April, he went via Ratnapura and Pelmadulla to Balangoda, in the neighbourhood of which place he stayed for some time, and then he took a trip over the hills to the lowcountry round about Bintenne. In this neighbourhood he stayed altogether ten days after which he made his way to Belihuloya, which he describes as most interesting country for Naturalists, the hills round offering fine scope for the insect-trappers. Here he collected some very good specimens, principally dragon-flies of scientific interest. Beetles were also plentiful in this part, and he was successful in obtaining some excellent specimens of the rare family of the *cetonids*, and also captured one or two of the leaf-butterflies, which are so seldom seen, and so difficult to catch when seen, owing to the practice they have when pursued of flying to a bush or a tree, where their peculiar color and shape, assimilating to the color and shape of the leaves render detection almost impossible. He speaks well of the capital resthouse at Belihul-oya, and what with the arrangements for one's comforts, and the excellent specimens he was enabled to secure, he retains some very agreeable recollections of his visit there.

On the 6th of May, Herr Frühstorfer went on via Haldummulla and Koslaude, to Wellaway, which he describes as an unhealthy and dirty place, principally occupied by Moormen. The jungle, however, was most interesting, and he collected some beautiful butterflies in this part, securing notably several specimens of the family known as *Papilios (montanus)*. His next move was in the direction of Hatton; and, in the jungle near the Kottiyagalle estate, he captured some splendid butterflies and an almost incredible number of grasshoppers. Here he collected, amongst other interesting specimens, a number of the insects which, from their red bodies and golden crests, are called "soldier" grasshoppers. Leaving Hatton, he came back to Colombo for a time, and, during the few days he was here, he made an excursion to Fanadure and the Bogodde lakes, where he found centipedes of all kinds, including many rarities. On the 8th of July, he journeyed to Kandy and Matale and on to Dambool, where he stayed a week, and where he gathered his best specimens of *orthopteras* or locusts, amongst them being some leaf-locusts of beautiful shape, and golden beetles, which are greatly in request by collectors and Museums. While in the neighbourhood of Dambool, he visited Anuradhapura, and then he went on, over Habbooreenna, to Kanthalai and Trincomalee, where he chiefly added to his store of butterflies. But Herr Frühstorfer has not been the only one working. He determined to do the thing on a large scale, so he has subsidized altogether fourteen other collectors (German or Sinhalese), who have been collecting for him in all parts of the island, and the result is that he has now a gigantic collection, the number of which he says it would be difficult to estimate; but he thinks he is well within the mark in saying that it includes 25,000 beetles, about 7,000 butterflies, about 3,000 *orthopteras*, a like number of dragon-flies, and a thousand spiders and centipedes. He has a lot of butterflies, and *orthopteras* that are not to be found in the Colombo Museum; while, numerically speaking, he says he has more than three times the number of dragon-flies to be seen there. Amongst his most valuable specimens are the leaf-butterflies and locusts and the long-horned beetles and *mantide*. Besides all these, he has a good collection of snakes amongst which are cobras, sea-snakes, and specimens of the *uropeltide* and false snakes. * * *

Herr Frühstorfer has secured specimens of both these kinds of snakes, including the *uropeltis grandis*, the strange and anomalous structure of which Tennent thinks leaves little doubt as to the origin of the fable of the transformation of the cobra. The color alone, he says, would seem to identify the two reptiles, but the head and mouth are no longer those of a serpent, and the disappearance of the tail might readily suggest the mutilation which the tradition asserts. Besides reptiles, Herr Frühstorfer, being also a conchologist, has a valuable collection of shells. For every specimen he has got, he says, he shall find a ready sale in the Museums of Europe; but the greater part

of his collection will be sent to the Berlin Museum, from which he has a large number of orders. One remark of his was of interest. It was that while Indian cobras are very common in German Museums there are not many from Ceylon, and they are in some request.

Speaking of the island as a field for Naturalists he says that it is very rich. He found the best beetles on the hills in the southern part of the island, and also the best dragon-flies, while he got the most butterflies there, too; but, for all *orthopteras* he found the best part was between Dambool and Trincomalee, although he says he has no doubt the change of the monsoon would make things *vice versa*.—Local "Times."

TOBACCO IN MATALE EAST.

(FROM A CORRESPONDENT.)

Where did you get part of the information about the harvesting of the tobacco on Wariapolla? It was premature: the truth is, that the manager is beginning to get rather anxious about the harvesting of the tobacco in the proper stage of ripeness; the showery weather has been so persistently against him, even on a dry day, work cannot be began until about 9 a.m., that is until the dew is off the leaves. The amount of labour required is enormous, as you can imagine, when you think there are about 34 acres with about 7,200 plants per acre, say $\frac{1}{2}$ million plants, and that two coolies can carry only 15 plants at a time and make, say, an average of 15 to 20 trips per day according to the distance. Then, for every ten men carrying about 5 men and women are necessary in field and drying shed, cutting the plants, attaching them to poles, and hanging up the poles with the plants suspended from them, in the factory. The amount of foresight and preliminary preparation is immense. Fancy the number of poles, about 12 feet long, and fairly straight, to take 250,000 plants, at 15 per pole. Then each plant requires a piece of rope or bark or withe, about 2 feet long, say 500,000 feet of cordage of some sort Wariapolla with its wealth of shrubs of all sorts, supplied the necessary 'cody' (what coolies call jungle rope) from the bark of cotton plants growing in a hedge. With the best of weather, *weeks* will pass ere all is housed and perhaps 2,000 men coolies be necessary.

THE GEMMING CONCESSIONS IN RAKWANA.

The following copy of a letter addressed by Mr. C. Shand to the Colonial Secretary anent the advertised sale of gemming concessions in Rakwana has been handed to us for publication:—

Colombo, 9th August 1889.

Sir,—With reference to the advertisement of the sale by the Government Agent of the Province of Sabaragamuwa of the lease for gemming purposes of a tract of land situated at Rakwana, I have the honor to inform you that in the opinion of those interested in the Rakwana district who also possess lands suited for gemming, 14 days' notice of the intended sale is far too short to admit of the full value of the lease being obtained.

There are at present in England several parties desirous of purchasing gemming concessions, and I think if time were given to enable them to bid at the sale, a much higher price would be obtained for the lease, than if it is sold in a hurry to native gemmers.

If the land in question is situated between Everton and Aberfoyle estates and bounded on the north by the Rangweltenne estate, it is, I believe, the most valuable gemming land in the island. The land I refer to is an extensive swamp, that at the foot of the mountains separating the Atakalan Korale from the Kolonna Korale, and the very reason the Government Agent puts forward for advising the sale, namely the impossibility of keeping out native gemmers, proves its great value.

I am only interested in the matter, so far, that I also have gemming leases to dispose of, and I do not wish to see them unnecessarily depreciated, by Government selling their leases much below their intrinsic value,—I have the honor to be, sir, your obedient servant,

C. SHAND.

The Hon. the Colonial Secretary, Colombo.

PLANTING IN CEYLON:—THE ORIENTAL BANK ESTATES COMPANY (LIMITED).

The third annual meeting of this company was held on the 18th instant at Winchester House, Old Broad-street, London, E. C. Mr. Alexander William Crichton, chairman of the company, presided.

The report of the directors and the notice convening the meeting were taken as read.

The Chairman: Gentlemen, this is the third time that we have had the pleasure of meeting you thus, but this occasion differs somewhat from the previous ones, inasmuch as it follows after only a short interval upon the two extraordinary general meetings that we held in the spring. It will be in your remembrance that those meetings were held with the object of preparing the way to obtain for our shares, according to the wish of the shareholders, a quotation on the Stock Exchange. The quotation was subsequently granted, and ever since then the shares have regularly appeared in the Official List. I will now proceed to lay the report before you, dealing with the general situation and with the amount of dividend we recommend you to declare. The report states the net profit, £25 803 16s 11d including £217 17s 5d brought forward from last year, and this profit is, besides, the amount written off the suspense account. And, gentlemen, we are glad to be able to meet you with such a result, for we have been put to great expenditure on our Mauritius estates from excessive rains at the beginning of the year; and we have also suffered heavily from the extraordinarily low prices of tea which have prevailed throughout the year, and which have prevented the expansion of the profit we had expected. As to the quantity of crop, indeed, the produce of our 4,200 acres of tea has increased very largely; but, notwithstanding this successful result of our agriculture, the heavy fall in the price of tea prevented a financial improvement commensurate with the increase in the crop. The measures which we took in view of this state of things will, we think, commend themselves to you. We have for some time past refrained from further extension of our tea plantations, so that our revenues should not have to bear the burden of the upkeep of new cultivation of plants which would not come into bearing, necessarily, for some years. Having, as we conceive, an ample area already planted, we devote our attention to increasing the yield per acre, and to improving the quality and manufacture of the tea; and in that direction lies, we feel sure, the best way of increasing our profits. (Hear, hear.) In this, it is true, we are not following the example nor the methods usual with Ceylon planters; but the failing of the planters too often has been to rush with enthusiasm and impetuosity into new undertakings without due regard to the teachings of experience. Hence arises a vast increase of production, depressing the market, but an increase springing rather from large areas rapidly and often imperfectly thrown into cultivation, than from large and satisfactory yields per acre of each estate. Hence, too, arises exaggerated notions of the value of the raw tea leaf by those who have to sell it for manufacture by others, 9 and 10 cents being asked for what, according to the probable value of the tea to be made from it, should only cost 7 cents per pound. We wish that all these tendencies were abandoned, and that everything were conducted with prudent anticipations of the future, so that the cost of production should fall well within the price to be reaped and thus a proper margin of gain be secured. These, at all events, are our objects, and we feel sure that the policy which we are pursuing will place the company in a much better position than rapid and costly extension. Increase of crop per acre, and the

improvement of quality rather than increase of acreage is what we aim at in our enterprise. (Applause.)

The report goes on to deal with the other products of our estates, and you will observe encouraging remarks with reference to the condition of the coffee trees, which conditions is more satisfactory from the high price which coffee now commands. With regard to sugar also you will see the good hopes that we have of a successful campaign during the coming season. The Mauritius sugar crop begins to be reaped in August and is finished about January, and during those months the crop being reaped a great part is made into sugar, and is gradually sent down for sale to Port Louis. Only a comparatively small part of last year's crop, therefore, benefited by the recent high prices of sugar, which were not obtainable there till nearly the end of April. But we are only reflecting the general opinion when we say we believe that a higher range of prices than has prevailed for some years will be obtainable for the next sugar crop, and that as a direct consequence of the small stocks now available for consumption. Some of you may have seen that lately the sugar market has weakened, but we are confident that that has only been in consequence of the proceedings of speculators. The sugar market is in an unusually strong condition, the stocks of the world being 300,000 tons less this year at this time than it was at the corresponding period last year, and that strong statistical position cannot fail to assert itself. The remarks on the crops and condition of our estates close all but the merely formal part of the report, and we have not again added to it this year the list of the names and acreages of our estates, for they have so often and recently appeared in reports and other published documents. Now, with regard to the accounts, there is little to call for fresh remark. The share capital remains as it was, except that a few more ordinary shares have been paid up, and I may remark that we do not intend in the future to issue any fresh shares. The acceptances and accounts payable are more than balanced by the value of stocks in hand and accounts receivable. A sufficient amount has been written off the suspense account. You will notice with regard to the item "office furniture, stationery, and stores," that has been increased by nearly £2,000, but the reason is that we find it more economical to purchase the stores here than in the colonies, and, therefore, we have purchased these stores as a means of reducing the expenditure on our estates. That does not mean expenditure in furniture, but stores purchased for the sake of economy. The only other item which requires examination is the amount by which the cost on our property has been increased; that is £24,000—of which £4,000 has been written—arising partly from recoveries and partly from a sufficient amount set aside to necessary depreciation of buildings and machinery. The increased cost of this property represents the value of certain mortgages taken over, which will yield us a good rate of interest; represents the costs of machinery, and so represents the cost of the one-third share of the Kondesalle estates, and a number of other smaller pieces of land which I mentioned last year, and which were paid for out of the year under examination. The profit and loss account resulted in a profit balance, which, added to the amount you have already received by way of interim dividend and to the amount written off for suspense account, makes a total of £26,803 16s 11d. Out of the balance we now recommend you to declare a dividend similar to the last, which makes a total distribution for the year of 7 per cent on the issue of preferred shares, and 5 per cent on the ordinary shares in proportion to the amount of capital paid up.

Adverting to the issue of our four and a-half per cent debentures, we are glad to say that the whole amount offered has been subscribed for, and we feel sure that this fresh capital will prove a source of great strength to the company. In the course of the operations of considerable magnitude in which we are engaged—I mean, amongst other things, the raising and bringing to market, either on our own account or

that of others, of crops of the annual value of more than £200,000—we have been obliged for a considerable part of the year to borrow large sums by way of advances, and these advances could only be obtained at the high rates of interest current in the colonies. But now, with this fresh and cheap, because well-secured-capital, we shall no longer stand in need of advances, and no longer, therefore, have to bear the burden of the heavy rates of interest heretofore entailed upon us. It is in view of the fact that the interest on these debentures will not be so heavy or so large in amount as that on the mere temporary advances, while the financial condition of the company will be incomparably more secure, that we have carried out this issue of debentures, and we have done so with success and economy. (Applause.) Turning now to another subject you will see from the report that we look for a recovery in the price of cinchona bark in the not distant future, and this we base on the fact that supplies on the present scale cannot be continued, at all events at present prices, for any length of time. The consumption of cinchona bark is very large, and is increasing year by year, although it is somewhat retarded by the high price charged for it—I mean 200 to 400 per cent. profit by the retailers—and this often amounts to a denial to the poor of this excellent drug. Great discoveries have recently taken place with regard to the action of quinine in cases of malaria fevers, which we all know cause such injury to health and such great loss of life almost throughout the world. This discovery has been confirmed, and is admitted by the scientific world, and it is that there is a microbe invariably concomitant with the malarial fever and, therefore in all probability the cause of it, and that this microbe is attacked immediately and destroyed by the administration of quinine, and that is proved to ocular demonstration. (Hear, hear.) The microbe infests the blood of the patient, and in an article in the *Nineteenth Century* for June, the observation of the microbe in the blood of the patient, and the effect of quinine upon it are described as follows:—"It is necessary for really good observations to draw the drop of blood from the finger of the patient"—that is, the drop of blood to be examined—"before quinine has been administered. This drug is so powerful a specific that it soon destroys the microbe at a mature stage of its existence, leaving the crescence only to disappear later. That this particular organism is the direct cause of the terrible changes which take place in the blood there can be little doubt, as the symptoms prove grave or slight according to the amount of destruction occasioned by its presence. Moreover, the progress of the disease can be checked by quinine directly influencing the life of the parasite." (Applause.)

Here, gentlemen, is a remarkable triumph for quinine. No other drug is in the same position. But it is not only on account of the excellence of the commodity, but from the fact that while the consumption is increasing the supply has a tendency to decrease, that we are warranted in saying that you have in your large cinchona plantations a property of great value and importance. (Cheers.) With regard to the Mauritius properties, you will, perhaps, remember that they have been managed on our account ever since we have been in possession, by Messrs. Ferguson and Weyms, who were, and are, the agents for the official liquidator of the old Oriental Bank Corporation. These gentlemen have been in charge of the interests of the liquidation all along, and they were, therefore, well acquainted with the circumstances and the peculiarities of our estates, and, consequently, it was desirable that they should remain in charge of them, at all events, for some time. But now we find that they are so much, and increasingly occupied with the estates and affairs of liquidation, and with numerous other matters, that we have thought it better that someone should be placed in charge of our business who was able to devote his whole time and attention to our interests, and Messrs. Ferguson and Weyms themselves occur in thinking this advisable. In September last, therefore, we sought the services of Mr. Frederick William Nash. He has had a life-long experience and knowledge of the sugar

trade, both in London and abroad; he has been in actual charge of a good sugar estate in the West Indies, and there he not long ago superintended the erection and successful working of new plant and machinery, embracing the modern improvements. We have received the highest testimonials in Mr. Nash's favour, and we believe him to be, without doubt, a person of great experience, ability, and high character. (Applause.) Mr. Nash studied the questions and accounts relating to Mauritius with us for some time, and then proceeded to Port Louis, where he assisted our agents and took over the management from them at the end of March. He has already won respect and confidence there and we hope that his counsels will be of benefit not only to this company, but to the interests of sugar generally in the island. (Cheers.) An important proposal has been made to us, through him, by the Mauritius Government—for the Government takes much interest in planting matters—that certain improvements in the manufacture of sugar, from which considerable additional profit is expected, should be carried out on one of our estates under Mr. Nash's supervision, and the Government making an advance of money for the purpose. (Hear, hear.) Mr. Nash starts on his new career under the best auspices, for the next crop promises to be an unusually abundant one, and as I said before, the price is likely to be much above the average. Indeed, in looking at the produce market, we cannot but think the prospects encouraging. Sugar, tea, and coffee all seem to be on the rise, and to command excellent prices—the prices of tea are improving with every report. In conclusion, gentlemen, I would remind our old shareholders, and I would point out to such as have lately taken interest in the undertaking, that the history of this company has been one of continuous progress. Starting at a time when things were involved in the difficulties of liquidation the old shareholders came together, and on such information as was supplied to them they chose these estates, out of the numerous properties of the old bank, as likely to yield about the best results. There have been—of course, in considerable undertakings, there will always be—difficulties and anxieties; but they are being overcome, economy is being enforced, the cultivation and methods of manufacture are being improved, and the condition of the estates is being everywhere perfected; and, notwithstanding the expenditure on all these things you have had a good return. It is by persevering on these lines with energy and determination that we trust to add further to the success and prosperity of the company. (Cheers.)

There being no discussion,

The Chairman then proposed the following resolution:—

"That the directors' report the statement of accounts to March 31st, 1889, now submitted be and are hereby adopted." Seconded by Mr. Grant Heatly Tod-Heatly, and carried unanimously.

It was proposed by the Chairman, seconded by Mr. Rohde, and carried:—

"That in accordance with the recommendations of the directors a dividend of three shillings and sixpence per share on the issued preferred shares, and of sixpence per share on the fully paid ordinary shares, and of a proportionate amount on the partly paid ordinary shares (making, with the interim dividend of a similar amount paid on February 1st last, a total payment of 7 per cent per annum on the issued preferred shares, and 5 per cent per annum on the ordinary shares in proportion to the capital paid up thereon for one year, ended March 31st, 1889), to be paid on and after the first day of August, 1889, upon the shares on the company's register at March 31st, 1889."

"That the retiring director, Mr. Grant Heatly Tod-Heatly be and is hereby re-elected," was proposed by the Chairman, seconded by Mr. Macdonald, and carried unanimously.

The auditors, Messrs. Quilter, Welton & Co., were re-elected, on the motion of Mr. C. F. Thomas, seconded by Mr. G. Field.

The meeting then terminated with a vote of thanks to the Chairman, proposed by Mr. Field, seconded by Major Speed, and briefly acknowledged.—*L. and C. Express*, July 19th.

A SUGGESTED NEW DEPARTURE IN CHINA TEA CULTIVATION.

Our contemporary *The Colonies and India*, in its issue received by the last mail, contains mention of a suggestion, which, if given practical effect to, must involve an entirely new departure in regard to the competition which India and Ceylon are carrying on with China in respect to tea cultivation. Reference is made in the columns of that journal to a letter addressed by Mr. William Cochran of Overdale, Dunblane, Perthshire, to the *Stirling Observer*, dealing with the present condition of the tea industry in China. This letter expresses the opinion that Chinamen require some practical lessons in the art of tea-making, and proposes the formation of a Scottish syndicate to undertake systematic cultivation of tea in China and to introduce a proper system for its manufacture. It is the first time, we believe, that we have ever heard of a proposal of the kind. Had the suggestion been confined solely to an attempt to introduce improved methods of manufacture we could understand it; but that it should embrace the actual cultivation of tea furnishes in our opinion ground for a foregone conclusion that any such enterprise, if undertaken, must be foredoomed to failure.

We have it already in evidence that at the low rates lately ruling in the home market for tea there is a loss of from 3d to 4d per lb. on all the tea sent from China to the London market. We have learned on Sir Robert Hart's authority that the greater proportion, indeed we may assume nearly all—of the tea sent to the West from the Chinese ports is produced by the peasants, each of whom is possessed of but a few bushes only. The rule seems to be that rice and other food products are grown in the levels of a farm, tea being cultivated on the higher grounds or ridges. It is fair to conclude from this fact that the mere cost of growing is very small, the charges which raise the cost of the tea before shipment being those incurred by intermediaries who collect the teas from the individual growers and by the manufacturers who prepare them. The idea of Mr. Cochran, of course, is to abolish these charges by intrusting the cultivation itself to a regularly organized company. Such an idea appears at first sight to be a warrantable one; but all those who have undertaken the cultivation of tea in India or Ceylon know the absolute cost of production and will probably be of opinion with ourselves that that cost must exceed any profit obtained or outlay made for the purpose of collecting tea grown by the natives, as we have said above, entirely, or almost entirely, without cost, the tea bushes occupying pieces of land fit for no other culture. If such a conclusion be correct, what prospect would there be of a company undertaking cultivation being able to compete with countries which, while the present rates are ruinous to China growers, are able at all events to obtain some margin of profit, however insufficient, upon such rates?

But such a consideration would not stand by our means alone in estimating the chances such a competition by China with India and Ceylon would have of success. So far as we are aware, no association of the character of that suggested has ever attempted to compete with the operations of the peasantry in China. The whole genius of that Empress opposed to any chance of success attending any such association. Competition of the kind, if attempted, we may be sure would arouse the fiercest opposition. The Government of China is—as it professes to be—parental. There is not an action of a Chinaman from his cradle to his grave that is not in some way or another subject to what Europeans term “grandmotherly legis-

lation,” and the first duty of the ruling power is to afford protection to native interests against any attempt to affect them by the intervention of the “foreign devil.” It is only in matters which it has become evident are essential to safeguarding the people against outside attack that the conservatism of the ruling power has in any degree yielded. They may have given way to the pressure of this necessity so far as to welcome tuition and guidance in the construction of armour-clad ships and the manufacture of other warlike agencies which they have been incapable of producing for themselves; but it would be quite another matter were the attempt made to introduce the thin end of the wedge which would eventually disrupt the whole course of any one of those pursuits by which the peasantry of the country earns its daily bread. We may be quite sure beyond this, that did the Chinese Government venture to sanction the commencement of any project such as Mr. Cochran has suggested, which must entail the possession of Chinese soil by the hated foreigner, there would be little chance of any trees planted being allowed to arrive at maturity. The fiercest prejudices would be aroused among the peasants who now sell the produce of the few trees they own individually, and the numbers of those affected would bring a pressure to bear on their Government which we may be certain would not and could not be disregarded.

It seems evident therefore that both the popular genius and the question of the cost of production oppose themselves to the initiation of any such scheme as that propounded by Mr. Cochran, and we should conceive that that gentleman must be profoundly ignorant of what would have to be contended against in any attempt to introduce it. We have said that had Mr. Cochran confined himself to the single proposal to essay the introduction of improved methods of manufacture we could understand the suggestion. But, after all, how could these be applied? If collection has to be made—as Sir Robert Hart informs us it has—from a multitude of growers, the operation must take time, and if that collection was to be of the raw leaf instead of as now of the prepared leaf, we may be certain of great deterioration before sufficient quantities could be brought to a central factory for treatment. The whole conditions of the tea-growing industry of China seem to be opposed to any chance of improving existing methods either of production or curing.

Sir Robert Hart has reported in favour of retaining the export duty on tea, and the mandarins would as soon part with existence as with the privilege of “squeezing” the productive classes. But foreigners, they well know, would protest against the export duty and refuse to be “squeezed.” We may, therefore, rely on it that concessions to foreigners such as are contemplated and would be necessary for the initiation of Mr Cochran's project, would be opposed to the utmost by the Chinese cultivators and the ruling classes alike. Competition of the nature indicated need not, therefore, be made a factor in estimating the future of tea in the markets of the world.

HOW I GOT TO HENARATGODA (AND SEVEN MILES SOUTH OF IT) FROM COLOMBO VIA VEYANGODA; AND WHAT I SAW:

COCONUTS AND PEPPER.

At the Henaratgoda station we saw about a dozen bales of kital fibre, regarding which we were told that the bales were taken somewhere “inland” to be sorted, cleaned and prepared for shipment. But

we think this must have been a mistake, and that the cleaning, sorting and final packing operations are conducted at Colombo.

At the base of one of the huge masses of rock which remain to speak of a range which once extended from Adam's Peak to the neighbourhood of Negombo, between the 4th and 5th mile on our nice minor road, we noticed a considerable grove of specially tall and straight areka trees, festooned up to 20 and even 30 feet with luxuriant pepper vines, which evidently found the nutriment, moisture, warmth and shelter they required in the great rock and the rich soil which ages of decomposition of mineral and vegetable matter had produced. Nothing could look more flourishing than the areka-supported pepper vines; but, for fruit-bearing purposes, it seemed to us that they were allowed to grow too far up. There must be difficulty, too, in gathering such berries as are produced. Only a few days previously Mr. W. H. Wright had told me that he grew pepper vines on areka-nut trees, but that he turned the branches downwards when the growth reached half way up. We have not yet grown pepper on areka trees on Eilandhu. The vine seems able to attach itself to the bark or surface of any tree, but with us it finds its special affinity in the jak tree, to the trunk of which (the lateral branches being pruned away) it adheres as tenaciously as ivy to an old wall or limpets to a sea-beaten rock. But evidently our chief crops are to be grown upon and gathered from the masses of rock and boulders which are scattered in such profusion on one elevated ridge that we have named it "the Necropolis." Many of the rocks are already covered or rapidly being covered with the vines, and if in periods of drought some of the branches of such rock-supported vines turn yellow, they recover with the first rains. The utilization of our rock masses, rich in felspar which is constantly decomposing, for pepper cultivation, I regard as a capital idea and likely to lead to a large success, if pepper only keeps up in price. A tamby who purchased our first gatherings at R14 per bushel now offers only R12, at which price we decline to sell, whether wisely or not, time will show. Like tea and all other plants in the lowcountry pepper cuttings or seedlings require to be well-shaded with ferns.

I never saw the tea looking fresher or better, and there is a prospect now of the almost interminable process of "supplying" coming to an end. One of Tangye's steam engines, which are equally famous on the Thames, the Nile, the Ganges and the Murray rivers, had found its way to this little estate of not much over 100 acres, and rolling by its agency and power was conducted for the first time on the occasion of our visit, August 6th. In looking at the engine, I was reminded that one of the interesting sights of the Melbourne Exhibition of 1880 was a similar engine by the same makers which had been successfully employed in the raising and shipping of "Cleopatra's needle." Truly steam, like a touch of nature, makes the whole world kin. As hard rolling seems to be one of the main requisites for making good tea, the next batch of Eilandhu leaf ought—state of market permitting—to sell at prices in advance of those hitherto received. I did not learn that the introduction of the steam engine had created any special sensation amongst the estate labourers or the villagers. They are a philosophical race, the Sinhalese, and cool to a degree worthy of high latitudes. I have not interfered with their right of way through the estate, their presence on which is not beneficial to some of its interests, but that is not enough: they want

me, exclusively and solely, to make and keep up a first class cart road for their benefit! This is an improvement even on the man who came and asked for the manure which had collected in the estate cattle sheds. He was as much surprised at the refusal, as was the man who planted a portion of my land with coconuts, at not being allowed to keep his appropriation. The young coconuts, by the way, which have been planted over the clean, tilled and appreciably manured land are growing luxuriantly, except the few which, notwithstanding all precautions, fell victims to the voracity of white-ants. All would have likewise perished, but for their retention in the nursery till well-grown, and the liberal application, subsequently, of ashes. The termites, no doubt, specially attack dying and dead matter, but tea planters in India (and partially in Ceylon) and coconut planters know to their cost that it is quite a mistake to suppose that living and healthy tissue is exempt from their destructive operations.

The bamboos (*Bambusa arundinacea*) grown from seed obtained from the Wynaad in 1877 (when vast forests flowered, seeded and died down), looked rich and beautiful with their curved and feathery tops. I have had letters about this fence of bamboo, in answer to which I have said, "Take warning by my sad experience." I ran bamboo shelter belts across the estate, which I had ultimately to remove at great expense of labour with catties, mamoties, picks and even fire. Nothing will grow within many yards around bamboos. We are compelled to dig a ditch inside the fence, and one of our neighbours is complaining of the upas-like qualities of our fair but fatal bamboos. Bamboos and acacia watties ought not to be grown near other vegetation.

PLANTING REPORT FROM THE HILLS OF CEYLON.

WEATHER AND FLUSHING OF TEA—CATTLE MURRAIN AND DIFFICULTY OF TRANSPORT—CEYLON TEA IN PARIS—CACAO CROPS AND BORER PEST—CUBEBS AT PERADENIYA—A BUDDHIST PRIEST AND HIS THRESHING-FLOOR.

6th August 1889.

What a time we are having with wet and cold. Every now and again the weather seems as if it were about to take up, and we were going to see a little more of the sun, but the rain comes back, and the wind seems as if it would never cease.

The effects on tea are marked enough by the railway returns; and not only has flushing nearly ceased, and the average dwindled down to all but unremunerative figures, but the bushes themselves look wretched, and shrunken and cold-like as the dripping coolies that work among them. When we have a return of bright weather, I fancy we will be kept amused with the rush that will have to be gathered.

Annoying as the present style of weather is to the planter, who would like to see the totals of his crop statement growing more rapidly, it is more easily borne than that of the man who has his tea ready to send away, but can't owing to the difficulty of getting carts. People who are near a railway fail to realize what murrain among cattle means. Prices good, tea ready to be dispatched, and no immediate chance of getting it away, are only part of the vexations to which those thus situated are subject. I know of some men, and there must be many more, who have got at present this added burden to the usual worries of a planter's life. The accounts which come to us from Paris of the manner in which the Ceylon teas are being pushed at the Exhibition there are deplorable; whoever is to blame. It will behove the Tea Fund Committee here to get to the bottom

of it; and although it is difficult to see how a bad bargain is to be remedied, still energetic efforts must be made to put things as far right as possible, if we are not to see accessions to those who have withdrawn their support from the Tea Fund. We have come to a nice state of things, when money voted for bringing our teas prominently before the French and other Continental peoples has resulted in subsidizing the liquor and barmaids of Messrs. Spiers & Pond and making a very secondary matter indeed of the tea itself. For my own part I cannot but regard the alliance of intoxicants and tea as a most unfortunate one and creditable to nobody, and although from being a teetotaler my opinion may be considered prejudiced, still I know of others outside of temperance circles who think with me, feel ashamed of the connection, and regard the arrangement as a decidedly bad one.

Cacao is looking well, and in many places bearing well. There is however a feeling of disappointment with some that the fine blossoms have resulted in so little fruit. Many people seem to regard cacao as uncertain a product as most other tropical ones; but when liberally treated—and therein I believe lies the true secret of cacao culture—it is as sure a stay as anything that can be found in the range of agriculture. It seems, however, to have a wonderful weakness for all kinds of pests, and at the present moment the borer is king. You hear of it all over the country, and the curious thing is that while some estates are sadly hampered by its presence, an adjoining one may be completely free of it. Whoever has got it will act wisely in proclaiming a crusade against its very existence, for the ability it displays in worming into the cacao pods, and through that into your profits, is something remarkable. Especially so in a wet season, like that we are now having; for in the borer's tract the rain follows, and the quantity of damaged cacao which that produces tells against any kind of fair estimate.

The medicinal pepper—cubebis I think it is called—which Dr. Trimen mentioned in his last report as so hard to get and for which he has hunted so long has at last been secured by the Peradeniya Gardens, and the few plants which have come are doing well, and have taken kindly to their new home. By-and-by, I fancy, plants will be offered for sale to the public; and if it is the real thing which has come, the wonderful fine price which this spice, from its scarcity, has been able to command will "sink at last into the common level of the world." If the general public are not grateful to Ceylon men for their unwearied efforts in reducing the price of all kinds of products which they touch they certainly ought to be. If we don't get thanks we have often little chance of getting ought else. What is wanted here, is to show the tropical product where there is a fair margin of profit to be got from its cultivation, and we at once tackle it, and cultivate so well, that the profit disappears.

I am in a difficulty. A Buddhist priest has written me about a threshing-floor which is on a piece of land I bought the other day, and which he claims. He says:—"May I request of you to proceed to the land, inspect and make inquiries and give up my floor, for without it I am not able to thresh the corn of my field which I have done for ages past." Is this Eastern hyperbole, or can it be that he alludes to his occupation in a former birth? PEPPERCOBN.

AN EX-CYLON PLANTER IN NATAL.

Mr. Douglas C. Pease writes to us from Natal on June 18th:—

"I trust you are still having prosperous times in Ceylon: tea no doubt is doing well for you in the lowcountry, but I should be surprised if it held out

so long as that upcountry. They talk here of the wretched Natal tea plantations, but I have not had an opportunity of going into the interior yet and having a look at the tea grown down here. Judging from the growth of other trees, willows and wattles and other Australian kinds, I should say tea should grow well. Funds permitting I should like very much to start a garden here. Although the opinion as to adaptability of climate is very varied: as far as I can gather the rainfall is not too great, in fact short of a heavy S.-W. monsoon month's fall of rain. The average I think is about 25 inches per annum to 32 inches." [Far too little for tea.—Ed.]

CASSIA LIGNEA AND CINNAMON.—If the producers of Ceylon cinnamon who complain of low and unremunerative prices could find consolation in the worse position of their competitors who have swamped the market with the inferior cinnamon known to commerce as "cassia lignea," they need only turn to the extract on another page headed "Low Prices of Produce." Cuprea, the other article mentioned, which at one time competed formidably with cinchona bark, is not even an inferior cinchona, but the bark of a plant belonging to a different order.

IMPROVING LAND NATURALLY.—Nature is always slow. Only man is in a hurry. Whoever talks about improving land in the natural way talks nonsense. It took nature some thousands of years, more or less, to produce the virgin soil that the people of this country have been exhausting. When it is exhausted what is to be done? Nature will do it if given time enough, but it may take a few hundred or even thousand years to restore old conditions. Man can do this in much less time, and with mankind time is money. Therefore the agricultural way is cheaper, as well as better, than nature's way. By manuring the market gardener makes land far more productive than it was in its original virgin fertility. In other words, man excels nature, which is not strange, as man has been improving on nature's works nearly ever since he has been on his planet.—*American Cultivator*.

PRODUCTS OTHER THAN TOBACCO grown in North Borneo were thus noticed in Mr. Fryer's Consular report:—

To turn from tobacco, which demands such large capital and is so risky, to other cultivations more likely to receive the attention of individual planters, Liberian coffee is the product which is being most cultivated. Near Kudat, Mr. Ohristian's estate is looking exceedingly promising, the first planted trees now barely two years old are crowded with berries and will be in bearing shortly; this estate is being considerably extended. Also at the back of Kudat several Hakka Chinese Christians who have settled there with their families have been planting Liberian coffee for some time past, subsisting in the meantime on the sale of bananas and pineapples which they have put in amongst the young coffee until it begins to grow up, these plantations also are being steadily increased. On the Benkoka River Mr. Leonards is commencing operations for a plantation which it is understood will be mainly of coffee, and on the Segulud River in Sandakan Bay the Planting and Trading Company's estate is coming on well, and new plants are being put in. In other parts of the territory one or two small plantations now several years old are in free bearing. Pepper at Bundo is yielding well. The export for the year is estimated to have been about 300 piculs (about 6,000 dol. worth), about four times as much as for the previous year, and the cultivation is being extended. At Sandakan a pepper garden is being started, while up the Kinabatangan the East Borneo Company proposes pepper planting on a somewhat large scale under the direction of Mr. Mitchelson, a well known Johore planter. The Planting and Trading Company's Manila hemp plantation is coming on well, and will soon be ready for the scutching machine, which however has not yet been erected.

SELLING TEA LEAF.

(To the Editor of the "Times of Ceylon.")

SIR,—There are many grumblers among sellers of leaf, and a very common expression with them is "if you won't give me more than 8 cts. per lb., I'll start manufacturing myself." For their benefit I beg that you will publish the following calculations, from which it will be seen that the extra profit to be derived from manufacture would hardly compensate them for the outlay in machinery, buildings, &c., to say nothing of the extra work thrown on the Superintendent.

PLUCKING TO SELL.	R	R
Ordinary upkeep, say, per acre	40	
Medium plucking, 1,200 lb @ 4 cts.	48	
1,200 lb leaf @ 8 cts.	—	96-00
Profit to seller per acre	8	—
	96	96-00

PLUCKING AND MAKING.

Ordinary upkeep and Plucking as above	88	
Making 22½ per cent=270 lb. tea @ 9 cts.	24-30	
Wear and tear of Machinery, Insurance &c. @ 2 cts.	5-40	
270 lb. at 47 cts, being equivalent of 9½d.	—	126-90
Profit per acre to manufacturer	9-20	—
	126-90	126-90

Haldummalla, May 28th.

D.

TOBACCO CULTIVATION AND MANURING IN CEYLON.

Now that tobacco cultivation is coming to the front in your island, I may as well allude to the best form of manuring for that rather exhausting plant. Many years ago I saw a good deal of native tobacco cultivation in the Negombo district, and did not fail to notice how assiduous the goyas were in their attention to the growing plants as regards water and manure. The former was supplied during the dry months by means of small bamboo spouts from wells dug at intervals in the land; manure was carefully applied by the hands of little children in the form of cattle refuse, ashes, and when procurable lime, in the form of burnt coral or shells. There is I believe very little doubt that lime is one of the best fertilizers for the plant; and on this point I may remind you that most of the tobacco land in the Jafna district, where the plant thrives so well, lies over a subsoil of coral, the gradual decomposition of which, no doubt, fertilizes the ground and saves it from exhaustion. I need hardly say that the native method of curing the leaf was not one that could be adopted by Europeans; more than this they invariably went in for quantity rather than quality and so allowed the leaves to grow large and coarse.—Local "Times."

RICE CULTIVATION IN CEYLON.

MUTURAJAWELA PADDY FIELDS.—The broad expanse of these fields is now under cultivation. The plants are now about 6 inches from the ground and a satisfactory crop is expected. The field is dotted here and there with "Wala Kumburas" which cannot be sown owing to their being full of water. So far Mr. De Mel, the enterprising merchant, deserves all praise for the success of his scheme; but I fear there will be a sort of barrier at certain seasons when perhaps his hopes may be damped. I refer to the season when there is a run of sea-water into the field, when all cultivation may have to be stopped. It is not only here that salt water forms a barrier against the successful cultivation of paddy crops. There is an immense extent of paddy fields in the Salpiti and Rayigam Korales, watered by the Bolgoda Lake, which suffers in the same way. This Lake, which covers a very large area, has a wide outlet at Panadura, which is a means of conveying the salt water inland at high tide, and it is thus distributed all over the lake. An immense tract of fields is left uncultivated when this happens. The goiyas about the

place have often represented matters to the Government but nothing has been done by it to prevent the influx of water through the rise of the tide. One cannot conceive how much the poor cultivators suffer owing to the neglect of Government. Only those who have been to the villages that border the immense Bolgoda lake and its branches could form an idea of the thousands and thousands of acres that are left uncultivated owing to the run of salt water into the fields. The judicious expenditure of a modest sum by Government at places where the sea runs inland into fields will set matters aright. Mr. Green, who takes such an interest in matters agricultural, would do well to impress upon Government the expediency of taking urgent steps.—Cor., "Examiner."

FRUIT AND VEGETABLE CULTURE IN FLORIDA.

In Florida, which must be a veritable land of Goshen as almost every fruit and vegetable that is good for anything is said to flourish there, the Sugar-cane is reported as one of the useful introductions, but grown mostly for retail purposes, being stripped and eaten mostly by children and the coloured race as a sweet-meat, and the sale for such is immense, realising about 2½d. for each stalk. Some little Sugar and syrup are manufactured on a small scale, but the cane is said to lack much of the rich, juicy saccharine matter of the Sugar-cane of the West Indian Islands, so that its quality and yield would never equal those of the West Indies. Florida, then, could not compete with these islands in the extended cultivation of the Sugar-cane for commercial purposes.

Sweet Potatoes grow well in Florida, are very largely grown, and are of much importance as a food product. The English Pea is largely cultivated, and does well; also a hardy Pea, called Cow-pea, is extensively grown. It is said not to be of a very delicate flavour, but highly nutritious, and produces a yield of 10 to 15 bushels per acre. The Cow-pea, put up in sacks and other packages, is quite an article of trade in some of the American markets.

The Ground-nut, or Pea-nut as it is called in America (Arachis hypogæa), is very largely grown in Florida. The plant thrives well in almost any soil, the cultivation is very simple, and the yield very productive, averaging about 100 bushels to the acre. The Spanish Pea-nut is now very extensively used in Georgia for feeding hogs; the average crop is about 125 bushels per acre. The hogs do all the harvesting and they generally eat the stems of the plant as well as the seeds. It is estimated that an acre of Spanish Pea-nuts will furnish four times as much hog food as an acre of corn. The Peccan-nut belonging to the genus Carya, the species of which, however, it not given, is said to be receiving much attention at present in Florida; it thrives so readily, and is so easy of growth, that it is suggested that it might flourish in many warm and tropical climates, such as the West Indies. The nut itself is planted and grows readily in any moderately good mixed soil of sand and clay. It is very hardy, and attains height, strength, and body from year to year, until it reaches a great size. The tree begins bearing at about eight or ten years, and the yield annually increases in quantity till the full growth of the tree is attained. The nut is a favourite one, and sells at about 5d. per pound.

Notwithstanding that nearly all our best-known fruits are cultivated in Florida, the Orange of course occupies the greatest amount of attention. The Orange groves in all parts of the State are rapidly multiplying and the bearing trees are now numbered by tens of thousands, while the young groves, which are being constantly started, comprise millions of trees. The Orange from the seed produces fruit in from seven to ten years, depending upon situation, culture, &c. Groves are made from wild stocks, usually cut off at a height of 3 to 4 feet from the ground, and the new shoots budded, generally produce fruit in three years. The number of Oranges produced from a single tree varies from 100 to 10,000 according to the age, situation, and treatment of the tree. The

trees are usually set 20 feet apart, and an acre will contain about 100 trees. At the present time a demand exists for twenty times the quantity supplied at 15 to 20 dollars per 1,000 as they hang on the trees.—*Gardeners' Chronicle*.

THE SINGAPORE BOTANIC GARDENS.

The Annual Report of the Gardens is published in last week's *Gazette*. As Mr. Ridley, the Director, did not arrive till late in the year, the Report is not as full as it otherwise would have been. There are many points of great interest dealt with, however, and we print below most of Mr. Ridley's report.

The exhaustive experiments in the cultivation of European vegetables, which was initiated and partly carried out by the late Superintendent, ceased in the early part of the year. It appears that although success attended the trial of some varieties, speaking generally, the result must be considered a failure. Great difficulty seems to be experienced in getting the Chinese market gardeners to take up the cultivation of European vegetables, or indeed of very newly introduced plants, despite the fact that the European population would readily purchase them.

The Report goes on to speak of the *Various Economic Plants* to which attention has been drawn.

Patchouly grows as easily and well here as in Penang, and from the above extracts it will be seen that by cultivation patchouly may well be one of the minor products of the Colony. Detailed information as to methods of cultivation has been supplied in answer to various enquires, but at the same time a caution has been given that the demand is limited, and that a large quantity thrown on the market would render it comparatively valueless, and that care should be taken not to grow it exclusively.

The Kew Bulletin for January gives a very full description of Coca with analysis of leaves received from Jamaica, St. Lucia, India, Java, Ceylon and British Guiana, from which it appears that leaves yielding 80 per cent. of the Alkaloid Cocaine are valued at 6*d.* to 8*d.* per pound. The plant grows very well here, and might be easily cultivated, but the demand is limited, and though small and exceptionally fine samples might find a market in Europe, the supply from South America is so large that, without further extension of cultivation, that country could swamp the cocaine market were it to send in one-eighth of the amount it could produce. From this it will be seen that extensive cultivation here would not pay, but small quantities might be grown at a profit.

There is a great demand for cubeb plants by planters just now, on account of the high price this pepper commands. It grows well in Singapore, but there is some difficulty in procuring the right species, as undoubtedly many of the plants sent out from Java as cubebes are merely forms of the wild and valueless *Piper carinatum*. A figure of the true species has been published in the Kew Bulletin, so that it can be now readily recognised by us.

The cultivation of pepper is steadily increasing and prices are well maintained.

The cocoa plants introduced from Trinidad through Ceylon in 1883 are now fruiting well, and there seems to be no reason for the plants being a failure here if properly cultivated. The series in Gardens comprises a considerable number of varieties, differing in colour and form of the fruit all of which seem to do well. It is probable that in parts of the Peninsula where the soil is richer than in Singapore the cultivation of this plant would be very profitable.

During the year, six varieties of the best kinds of tapioca used in British Guiana were received. They are highly esteemed in South America, and form a considerable portion of the food of the natives. They have grown very well here, and we have now a sufficient stock for distribution.

The various kinds of rubbers mentioned in former Reports continue to grow well. There is at present, however, little demand for young plants, a circumstance which would seem to point to the necessity of Government planting largely, as planters, as a rule, prefer to

plant crops having a quicker return. Meanwhile the consumption of rubber is increasing, and it seems probable that with only natural reproduction to meet the demand, at no distant date the supply will become very limited.—*Singapore Free Press*.

CITRONELLA OIL.

Some correspondence has lately appeared in Ceylon journals concerning the alleged adulteration of citronella oil with kerosene by the native growers. A native correspondent points out that a short time ago about 650 cases of kerosene oil arrived by boat at the Weligama Custom-house from either Galle or Colombo, and that about three-fourths of this quantity was straightway forwarded to Matara, Akuressa, and Kumburupitiya. All these places are in the southern part of the island, which is the one where all, or nearly all, the citronella oil is now manufactured. As it is improbable that the native inhabitants of the districts referred to would be in want of such a large quantity of kerosene oil for illuminating purposes, the correspondent infers, or rather he plainly states, that it is employed for adulterating citronella oil, which is subsequently sold as a pure oil to the European merchants in Galle or Colombo. The writer concludes as follows;—"If European merchants think that the citronella oil as supplied them by their contractors and that supplied direct by the proprietors of citronella estates are the same, they make a great mistake; for the oil supplied by proprietors and manufacturers is pure and free from any adulteration. It will now strike European merchants as strange that, in the contracts which they entered into between themselves and the contractors, there is generally a conditional clause to the effect that the oil supplied by contractors will be *market oil*. If any dissatisfaction is ever expressed by a merchant as regards the oil thus supplied, the contractor's plea is that it is market oil, and that he is not responsible for its quality; but such an excuse could not be made by a proprietor."

With regard to this assertion, a gentleman who is said to be one of the best authorities on citronella oil in Ceylon states that as far back as 1883 he had his attention called to the practice prevailing among natives of adulterating citronella with kerosene—a sophistication which could not be detected, he states, even if carried out to the extent of 25 per cent.; and an English buyer of citronella oil on a very large scale adds that he could not find any pure oil whatever in the market. Whether adulteration of citronella is really carried on to the extent and on the systematic plan which these correspondents' letters would seem to indicate may still be open to some doubt, but it is quite certain that unless some such practice is resorted to it cannot pay the natives to manufacture or the merchants to export the oil. Like most other cultures which have been taken up in Ceylon on a large scale, the cultivation of citronella oil has been overdone. At present what are known as "native" brands are selling in London at $\frac{3}{4}$ *d.* to $\frac{1}{2}$ *d.* per oz., or, to calculate it in an easier way, at 10*d.* to 1*s.* per lb.; and the exports from Ceylon, in spite of the low prices, which have now existed for a considerable period, continue to increase. It has been recently stated on good authority that a citronella plantation, according to the amount of care bestowed upon it yields from eighteen to twenty-four bottles per acre per crop. There are, in the most favourable circumstances, three crops annually, usually about March, July, and December, and an acre of grass may, therefore, be estimated to yield from forty-five to seventy-two 22-oz. bottles, or from 60*s.* to 95*s.* worth of citronella per annum. Out of this scanty return, distilling, packing, freight, and the profits of at least three middlemen have to be paid, and there cannot, therefore, in the most favourable case, be any but the barest margin of profit left for the cultivator. A further proof of the unremunerative nature of the citronella industry is that at least one of the principal European firms of distillers is said to have withdrawn from the market some time ago, when prices were still considerably higher than they are

now, because they no longer found it profitable to manufacture this oil. The "F & K" brand of citronella enjoyed a high reputation for purity on the European markets, but we think we are right in stating that it is no longer manufactured now. Another English grower in Ceylon, Mr. Winter, whose oils are equally highly esteemed, still continues, we believe, to manufacture citronella, or did so until recently, but we doubt whether he will be able to continue to do so remuneratively at the present market prices. A third very highly esteemed brand is that of Mr. Fisher, of the Perseverance Estates, Singapore. His plantation was started some twenty-five years ago as an essential-oil farm, and covers a very large area, its production in various essential oils, principally nutmeg, citronella, lemon-grass, patchouly, &c., amounting at one time, it is said, to an aggregate of 200 lb. per day. The European makers always command very much higher prices for their oils than the natives do, and if the former, with their superior facilities, better machinery, and larger capital, cannot make money out of citronella any longer, it is clear that the chance that the native growers can turn out a pure oil at the present prices are very slight indeed. It is not forty years since citronella was first imported into this country for commercial purposes, and since that time it has become one of the most popular perfumes, and certainly by far the most extensively used in soap-making. In 1864 the exports of citronella oil from Ceylon had already attained the figure of 622,000 oz., in 1872 they were 1,595,000 oz., in 1881 1,761,000 oz., last season 9,508,000 oz. and for the six months which have elapsed of the season now running they have already mounted up to 7,666,000 oz. These figures do not take into account the production from other sources, such as Singapore and Southern India, which would perhaps amount altogether to 15 per cent. of the Ceylon production. It seems certain that the increase in the consumption of the oil cannot have held pace with the production, and stocks must therefore have accumulated to a considerable extent. This is probably the case in America more than here, as most of the citronella oil now takes its way to the States. It is a peculiar circumstance that while lemon-grass oil, which is so closely allied to citronella in its character and the purposes for which it is applied, and which has usually been much more expensive than citronella—its production being very much smaller—was actually dearer than the latter oil in the years between 1881 and 1885. In 1881 or thereabouts the United States first commenced to use citronella oil in very large quantities, and their demand stimulated the production of the oil, which at that time must have been a very profitable article to the cultivators. Between 1858 and 1862 the price of the usual brands of citronella oil ranged from 2½d. to 4½d. per oz.—occasionally a little higher, and that of lemon-grass between 4½d. and 7½d. per oz. At one period during 1863 the prices advanced to 7¾d. for citronella and 9d. for lemon-grass, which are the highest quotations on record. This advance greatly stimulated the cultivation of the grasses. During the last eight years the general range of prices, not counting occasional deviations, has been as follows:—

	1880	1881	1882	1883	1884	1885	1886	1887
Citronella	4d.	3d.	2½d.	2¼d.	1¾d.	1¾d.	1½d.	1d.
Lemon-grass	3½d.	2½d.	2½d.	2½d.	1¾d.	1½d.	1½d.	1¾d.

and, for citronella, still further downwards to its present quotation. There does not seem much prospect of any satisfactory increase in the market value of citronella oil until it has first reached a point so low that some of the native growers shall be absolutely compelled to cease distilling altogether. It might be thought that at present that limit was already reached, but the shipments still continue to grow, and such does not therefore appear to be the case. When once the position has been cleared by the process of eliminating a number of people who now distil the oil, the market may again revert to a fairly satisfactory position for a while, and the European growers be able to obtain fair prices for a good article. It is stated on good authority that there are at present soap-makers in the States who consume over 1½ million ounces of

citronella annually, and there is consequently a large enough market for the article if its production is kept within reasonable bounds. It will be to the interest of the Ceylon merchants and exporters to assist in the suppression of the adulteration of citronella; and for this purpose we hope to give further particulars in an early issue regarding the detection of the adulteration by simple means.—*Chemist and Druggist.*

FRUIT CANDYING IN ITALY.

A good deal of interest has been drawn of late years in fruit-producing countries, especially in some of our colonies, as to the best mode of preserving fruits for exportation. That of preserving them in syrup in hermetically sealed tins has been found to answer well, and has become very generally adopted; but the process of candying with sugar is felt in some countries, and with some fruits, to be preferable, consequently enquiries are frequently made as to the *modus operandi* adopted in fruit candying countries on the continent, about which little seems to have been known out of the country where it is practised.

The following account of this industry, which has just been drawn up by the British Consul at Leghorn, will, therefore, we doubt not, be of considerable interest to our readers, especially to those in sugar producing countries. Mr. O'Neill says, "It would be a mistake to suppose that Leghorn is a great centre for this industry in all its branches. The candying of fruits, whole or cut, is carried on at many other places to a larger extent. At Genoa, and westward along the French Riviera, at such places as Grasse, this industry is carried on, and we know that in Spain and Portugal fruits are also candied, Madeira being especially noted amongst the possessions of the latter for this manufacture.

Moreover, upon inquiry, I find that in this city of over 100,000 inhabitants only seven establishments are occupied in the manufacture, and that these seven, when in full working, only employ about 200 hands, Leghorn can hardly, therefore, be considered a great centre of the fruit candying industry.

It does, however, I believe, occupy the first place in Italy, and, perhaps, throughout the Mediterranean for the preparation of the candied Citron and Orange peel so largely used in all branches of confectionery; for the Citron is brought to us for this purpose from Corsica, from Sicily, from Calabria, and other southern provinces of Italy, from Tunis and Tripoli, and even from Morocco, and the candied peel of the fruit is exported hence to North America, to the United Kingdom, and to Hamburg, for distribution throughout Germany. Sugar also is imported for the purpose of the manufacture from Egypt. The wood of the boxes in which the candied peel is packed reaches us from Trieste, and the immense earthenware vessels necessary for the saturation of the fruit in Sugar syrup are made in the neighbourhood of Florence. On all sides, I hear that Corsica produces the Citron of the finest quality those of Sicily and Calabria are regarded as slightly inferior, whilst that which comes from the African coast is held in still lower repute, and, indeed, appears to be of a different variety, being larger, and having a smooth instead of the rough, granulated surface generally characteristic of the Citron. The African Citron is probably somewhat deficient in the essential oil which forms the medical property, and gives the flavour to the rind. The Oranges imported into Leghorn, whether for consumption or for candying, are nearly all brought from the islands of Sicily, Sardinia, and Corsica.

I shall, perhaps, convey the clearest impression of the treatment of the fruit, and the process through which it passes, if I follow it through the various stages of its preparation, from its arrival at this port to the moment of its departure hence in cases filled with boxes neatly packed with the cut candied peel.

In all the countries I have mentioned above as contributing the raw fruit for this industry, it is treated in the same manner for the over-sea passage. The fruit is simply halved, and placed in hogsheds or large casks filled with a fairly strong solution of brine, the fruit

being halved merely to ensure thorough preservation of the rind by an equal saturation of the interior as well as the exterior surface. In these casks it arrives at the doors of manufactory.

The first process to which it is then subjected is the separation of the fruit from the rind. This is done by women who, seated round a large vessel, take out the fruit, skilfully gauge out the inside with a few rapid motions of the forefinger and thumb, and, throwing this aside, place the rind unbroken in a vessel alongside them.

The rind is next carried to large casks filled with fresh cold water, in which it is immersed for between two and three days to rid it of the salt it has absorbed. When taken out of these casks, the rinds are boiled with the double object of making them tender, and of completely driving out any trace of salt that may still be left in them. For this purpose they are boiled in a large copper cauldron for a time varying from one to two hours, according to the quality of the fruit and the number of days it has been immersed in brine. When removed from this cauldron, the peel should be quite free from any flavour of salt, and at the same time be sufficiently soft to absorb the sugar readily from the syrup, in which it is now ready to be immersed.

The next process to which the rind is subjected is that of a slow absorption of sugar, and this occupies no less than eight days. Needless to say that the absorption of sugar by fresh fruit in order to be thorough it must be slow, and not only slow, but it must also be gradual—that is to say, the fruit should at first be treated with a weak solution of sugar, which may then be gradually strengthened, for the power of absorption is one that grows by feeding. The fruit (and this holds good more especially with the rind) would absorb with difficulty, and more slowly and unequally if plunged at once into a thick syrup, than if gradually treated with weak solution, easier of absorption, and by which it has been thoroughly permeated first. It is a knowledge of this fact that governs the process I now describe.

The fruit has now passed into what I may call the saturating room, where on every side are to be seen long rows of immense earthenware vessels about 4 feet high and 2½ feet in extreme diameter, in outline roughly resembling the famed Etruscan jar, but with a girth altogether out of proportion to their height, and with very short necks and large open mouths. All the vessels are filled to their brims with Citron and Orange peel in every stage of absorption, i.e., steeped in sugar syrup of, roughly speaking, eight different degrees of strength. I said before that this is a process that occupies almost always eight days, and as the syrup in each jar is changed every day, we may divide the mass of vessels before us into groups of eight. Take one group of this number, and we are able to follow the fruit completely through this stage of its treatment. With vessels of such great size and weight, holding at least half a ton of fruit and syrup, it is clearly easier to deal with the syrup than with the fruit. To take the fruit out of one solution, and to place it into the next stronger, and so on, throughout the series, would be a toilsome process, and one, moreover, injurious to the fruit. In each of these jars, therefore, is fixed a wooden well, into which a simple hand suction-pump being introduced, the syrup is pumped from each jar daily into the adjoining one.

"How is the relative strength of the syrup in each jar regulated?" is the next question.

"The fruit itself does that," is the foreman's reply; and this becomes clear from the following explanation:—Number your group of jars from 1 to 8 respectively, and assume No. 1 to be that which has just been filled with peel brought straight from the boiler, in which it has been deprived of the last trace of salt, and No. 8 to contain that which, having passed through every stage of absorption but the last, is now steeped in the freshly prepared and therefore the strongest solution of syrup used in this stage. "We prepare daily a syrup of the strength of 30°, measured by the 'provino,' a graduated test for measuring the density of the syrup," continued the foreman, "and that is poured upon the fruit in jar No. 8. Tomorrow the syrup from this jar weakened by the

absorption from it, by the fruit, of a certain proportion of sugar, will be pumped into jar No. 7, and so on daily through the series. Thus, No. 1 containing the fruit itself regulates the strength of the syrup, as I said." "But if the syrup has lost all its strength before the seventh day, or arrival at jar No. 1?" we ask. "Care must be taken to prevent that, by constant testing with the 'provino,'" is the reply; "and if that is found to be the case, a little stronger syrup must be added to the jar."

A slight fermentation next takes place in most of the jars, but this, so far from being harmful, is regarded as necessary, but of course it must not be allowed to go too far.

There is yet another stage, and that, perhaps, the most important, through which the peel has to pass before it can be pronounced sufficiently saturated with sugar. It is now boiled in a still stronger syrup, of a density of 40° by the testing-tube, and this is done in large copper vessels over a slow coke fire, care being taken to prevent the peel adhering to the side of the vessel by gentle stirring with a long paddle-shaped ladle. The second boiling will occupy about an hour.

Taken off the fire, the vessels are carried to a large wooden trough, over which is spread a coarse, open wire netting. The contents are poured over this, and the peel distributed over the surface of the netting, so that the syrup—now thickened to the consistency of treacle—may drain off the surface of the peel into the trough below. The peel has now taken up as much sugar as is necessary.

Now comes the final process, the true candying of the covering of the surface of the peel with the layer of sugar-crystals which is seen upon all candied fruits. To effect this a quantity of crystallised sugar—at Leghorn the same quality of sugar is used as is employed in the preparation of the syrup—is just dissolved in a little water, and in this the now dried peel, taken off the wire netting, is immersed. The same copper vessels are used, and the mixture is again boiled over a slow fire. A short boiling will suffice for this, the last process, for the little water will quickly be driven off, and the sugar upon cooling will form its natural crystals over the surface of the fruit. Poured off from these vessels, it is again dried upon the surface of the wire netting as before described. The candying is now complete, and the candied-peel is ready for the packing-room, to which it is carried off in shallow baskets.

In the packing-room may be seen hundreds of boxes of oval shape, or, if I may so speak, of rectangular shape, with rounded corners, and of different sizes, for each country prefers its boxes to be of a particular weight, Hamburg taking the largest, of 15 and 30 kilos., United States of America preferring smaller, of 10 and 12 kilos., whilst England takes the smallest, of 5 kilos., and one containing about 7 English pounds. The wood of which the tops and bottom of these boxes are made comes to us in thin planks from Trieste, and a skilful packing is generally done by women, and the boxes are lined with white paper. They are then packed in cases of 100 kilos., 10 of the smaller American boxes filling a case. The candied peel is now ready for export.

I think I have now spoken of all that need be noticed in the actual manufacture of candied Citron and Orange peel at Leghorn. There are, however, a few reflections upon the very existence of this industry here which seem to me suggestive and instructive ones. In my inquiries into the course of the industry I find that the fruit itself, and every ingredient and article necessary to the preparation of the candied-peel comes to us from abroad. The fruit of the best quality is from Corsica; Egypt furnishes the sugar. England provides the fuel, distant provinces of Italy contribute a portion of the raw product and the wood for the boxes in which the peel is exported. The province of Leghorn provides nothing but the labour necessary to the manufacture. Nor is this industry one that has fallen into Livornese hands from any specially acquired local handicraft or skill. How, then, does this industry exist here in these days of keen international competition? No doubt it is mainly supported

by the large drawback granted by the Italian Government upon the duty paid on the chief and dearest ingredient in manufacture—sugar. The Customs tariff in force imposes a duty of 76/75 lire upon 100 kilos. of the sugar used (classed in the tariff as of second class), but grants a drawback of 60/50 lire upon 100 kilos. of the exported article. Without this large measure of support there can be no doubt this industry would immediately and wholly collapse. With it even, it finds it difficult to hold its ground. Exporters tell me that the United Kingdom is beginning to call for the fruit to be sent to it direct from the countries of production in the same condition that it reaches Leghorn, viz., steeped in brine, and the manager of one of the factories I visited confirmed this with an air of very natural chagrin by telling me that he had himself seen 600 hogsheads of fruit shipped in brine in one vessel last year from Bastia for England.—*Gardeners' Chronicle*.

REPORT ON TEA CULTURE IN ASSAM FOR 1888.

In the Brahmapootra Valley, the sub-division of Dibrugarh shows the largest area under tea grants (113,029 acres), and in the Surma Valley the sudder sub-division of Cachar comes first with 178,639 acres. The largest outturn is, however, reported from Dibrugarh, not Silchar.

Omitting the Khasi Hills, where the area under tea is altogether insignificant, there was an increase in the area held by tea-planters in every district except Durrung, Nowgong, and Sibsaugor. In Cachar, the area is believed to be below the truth, as land leased for tea-growing, from private individuals has not been included. In Sylhet, the figures received from managers have been used, as much of the land under tea being rented from zemindars, cannot appear in the district registers. In Durrung the decrease is mainly due to a revision of the register. In Nowgong, the alteration is caused by the resignation of two 30-year Lease Rule grants, and the closing of two gardens. In Sibsaugor, the decrease was due to the closing of gardens. In Luckimpore, there have been considerable extensions, hence the increase in area. Managers or agents furnished figures for 797 out of a total of 863 gardens. Deputy-Commissioners made estimates for 62 gardens, and for 4 no information was forthcoming. Last year managers or agents gave figures for 822 gardens and Deputy-Commissioners were obliged to estimate for only 47. The decrease in the number of gardens from which returns were obtained is partly due to the earlier date at which they were called for, and the greater punctuality which was required from Deputy-Commissioners. In many gardens figures for 1888 are not available in March 1889, and estimates have to be resorted to. In Habiganu, Jowai, Dhubri, Goalpara, Gowhaty, Mungledye, Nowgong, Golaghat, Dibrugarh, and North Luckimpore figures received from every garden, except a few in Gowhaty managed by natives. In Cachar, out of 181 gardens, statistics were obtained for 160, for 14 the figures of 1887 were taken, and for 1, newly opened, no figures could be had. In Sylhet, managers furnished figures for 101 gardens, the Deputy-Commissioner made estimates for 11, and for 3 no returns were obtainable. In the Dibrugarh sub-division one manager declined to furnish figures. In Sibsaugor, returns were obtained from 167 gardens, and estimates made as to the remaining 9. In the Tezapore sub-division managers or agents furnished figures for 47 gardens, and the figures of 1887 were repeated for the remaining 7. The thanks of the Chief Commissioner are due to those managers and agents who have assisted in the compilation of this report by furnishing the statistics required. Without the cordial co-operation of the tea planters, it is impossible for Deputy-Commissioners to furnish reliable statistics, and unless these are obtained, much valuable information is lost to the planting community.

The increase in area under mature plants was large (10,429 acres) and occurred mainly in Sylhet where

it amounted to 5,103 acres. This increase means a corresponding decrease in the area under immature plants. This was, however, partly made up by extensions, amounting to 5,597 acres, thus leaving a net decrease in the area under immature plants of 4,832 acres.

The increase in the area of tea under cultivation was greatest in Sylhet, and is due there, as well as in Cachar, to extensions, mainly in the *bill* lands, which have been found to yield so well of late years. The greatest falling-off was in Kamroop, where the loss of 682 acres is unaccounted for by the Deputy-Commissioner. In Goalpara, Nowgong, and Sibsaugor the decrease was due to the closing of gardens. In Luckimpore, extensions have been pushed on as much as possible to lessen the cost of supervision and manufacture. The total outturn of tea from the Province is reported as 72,677,982 lb, which amount to an increase of 4,378,524 lb., or 6.41 per cent. on the figures for the previous year. The estimate of the Indian Tea Association for the outturn of the total Assam crop of 1888 was 69,209,004 lb., or nearly $3\frac{1}{2}$ million lb. less than the estimate given in this report. This Province, according to that Association's figures, produced 71.86 per cent. of the total amount of tea grown in India. As usual the trade figures are the lowest, and those sent by Deputy-Commissioners the highest. Probably those furnished by the Tea Association are the most reliable. It is natural that the trade returns should be the lowest, for out of the total amount produced a certain quantity must be retained for local consumption. The figures point to a steady growth in production. All districts except Cachar and the Khasi Hills show an increase, as compared with the figures of the preceding year. The decrease in Cachar is attributed to the very unfavourable weather and the prevalence of blight. Throughout the greater part of the Surma Valley, the early part of year was too wet and the close too dry. A leading planter in Cachar, quoted by the Deputy Commissioner, writes as follows:—

"During the year the weather proved most unfavourable for both growth and manufacture. The season was very wet, and for months we had rain every day. Then the dry weather set in early, and there has been hardly any rain since the beginning of October. Hail was very destructive in places, and many Cachar gardens suffered severely, while, from the unusual rainfall, all low gardens having drained flats had their outturn greatly reduced. The rain falling daily rendered the soil quite sodden, as there was little heat, and in most instances the drains stood brimful in parts, as they had not been constructed to carry away such an abnormal fall of rain. Tea gardens did not suffer in proportion so much from the wet, but they too were terribly handicapped, and to make matters worse, this very hard weather seems to have been chiefly confined to the Surma Valley districts. Many places in the Assam Valley did remarkably well, and had good weather. Red spider was very prevalent, and more destructive than ever. In some places old plants actually died out, and in all cases it took time for the bushes to recover from its ravages. The mosquito blight was as bad as usual, but not worse."

In Sylhet, also, the weather was everywhere unfavourable, and the crop not up to the average. Heavy rain, and absence of the steamy heat so essential to the growth of tea, distinguished the beginning of the year, and unusual drought marked the last two manufacturing months. Red spider also proved very destructive. On the whole, however, notwithstanding these difficulties, the outturn in this district is estimated to have shown an increase on that of the preceding year, owing mainly to the improved yield from plants classed last year as immature. In the Brahmapootra Valley, the year was a favourable one in all districts, though some damage was done by hail in Sibsaugor. The Deputy-Commissioner, Luckimpore, writes—

"On the whole the year 1888 has been favourable for tea. The rainfall has been somewhat below 1887, but notwithstanding this, June to September were

splendid tea months, and nearly every single garden has made more than its estimate."

The table below gives, according to the district returns, the yield per acre for the Brahmapootra Valley, Surma Valley, and whole Province:—

	Yield per acre.	
	1887.	1888.
	lb.	lb.
Surma Valley	379	349
Brahmaputra Valley	388	415
For the whole Province	384	386

These figures are the natural result of the character of the season. In the Surma Valley, the average outturn in Sylhet, owing probably to the productiveness of the gardens lying in drained *bils*, is greater than in Cachar. In the Brahmapootra Valley, Luckimpore, as usual, heads the list, owing to its great humidity. The hot winds, comparatively so-called, which blow in March and April in Kamroop and the Western end of the valley, and so considerably retard the early flush, are unknown in the North-eastern districts, where plucking consequently generally begins earlier than in any other part of Assam.

The figures for average outturn of the Indian Tea Association given below, though somewhat lower than those brought out by district returns, nevertheless confirm generally the results shown in the preceding statement:—

	Yield per acre.	
	1887.	1888.
	lb.	lb.
Surma Valley	352	329
Brahmapootra Valley	376	398
For the whole Province	365	367

The trade return figures for the import and export of tea-seed are given in the statement below:—

	Imports.		Exports.	
	1887.	1888.	1887.	1888.
	Mds.	Mds.	Mds.	Mds.
Surma Valley	102	392	1,602	3,337
Brahmapootra Valley	2	4,053	8,734
For the whole Province	102	394	5,655	12,071

It would seem from these that the revival in the trade noted last year continues, and is accentuated. The amount exported, though large, does not equal that of the year 1884, when, owing to the demand in Ceylon, the total rose to 15,490 maunds. No reliable information can be expected from district returns as to the cost of production and cost of cultivation. The figures must necessarily vary from garden to garden, but the limits of the variations are in some cases so great as to show that there must be gross error somewhere. On this subject the Deputy-Commissioner, Luckimpore, writes as follows:—

"I have again not filled in the columns of the return relating to cost of cultivation and manufacture. The figures supplied by the managers vary so considerably that it is impossible to form any accurate estimate. One planter gives the cost of cultivation per acre at R10 and another at R210, while the cost of manufacture varies from 4 annas to 8 annas per pound. However, from what I can gather, it costs from 3½ to 6 annas per pound to place the tea in Calcutta and 7 to 10 pence in London."

Taking the estimates given by Deputy-Commissioners, we obtain the following figures:—

	Cost of cultivation per acre.	Cost of production of 1 lb. of tea laid down in Calcutta.		
		Rs.	As.	P.
Cachar	58	0	6	4
Sylhet	67	0	7	9
Goalpara	not given	0	6	0
Kamroop	27	0	6	0
Durrung	72	0	7	4
Nowgong	100	0	6	0
Sibsangor	89	0	5	6
Luckimpore	100	0	5	0

It is impossible to reconcile some of the figures in the last column of this table with those in the column preceding and the outturn. The mode in which the cost of cultivation is calculated clearly requires consideration. The average prices obtained in Calcutta, for the teas of 1888 are stated by the Indian Tea Association to have been 7 annas 5 pies to 7 annas 7 pies per pound for the Surma, and 8 annas 2 pies per pound for the Brahmapootra Valley. The teas of 1887 fetched the following average prices on the total number of reported sales:—

Surma Valley 7 annas 9 pies to 8 annas per lb. Brahmapootra Valley 8 annas 2 pies per lb.

These figures represent actuals, and are reliable as far as they go, but it must be remembered that all Assam tea is not sold in Calcutta, and that many gardens send their produce direct to London. No reliable figures are as yet obtainable as to the average prices realized in London, but as the Calcutta averages are somewhat below those of last year, it is but too probable that there has been a decrease in the London market. As usual the change is attributed to excess of production as compared with consumption.

The season was unfavourable to tea in the Surma Valley, and favourable on the Northern side of the central range. Cachar was almost water-logged, while in Sylhet the rainfall was excessive, and its distribution bad. The following extract from the Report of Mr. Driberg, Deputy-Commissioner of Luckimpore, is interesting, as indicating the opening of a new, though limited, market for the poorer kinds of Assam tea:—

"During my recent tour in the Mofussil, I saw about a couple of maunds of loose unpacked tea at a Kaiya's. On making enquiries I found that he bought it from villagers, who have small plots of tea, some in the *bastis*, some in the jungles, on old abandoned gardens. A ryot takes a *biga* or so of an abandoned garden, keeps it clear, plucks the leaf, manufacturers it and sells it to the Kaiyas. The Kaiya in question told me he got some 10 maunds each year in this way, and another Kaiya, to whom he referred me, said he got about 15 maunds. I afterwards, when inspecting a tea-garden in the neighbourhood, heard from the manager that many ryots have small patches of tea, and that the Kaiyas collect some 200 maunds of tea annually. The Kaiyas told me they bought at 5 annas per seer, and after sifting and sorting, they sold at 12 annas a seer. Most of this tea goes to Margherita, and is purchased by the Singphos and Khamptis. I was not aware before that the ryot went in for tea cultivation in this way, and that the hill people bought so largely from us. It has hitherto been supposed the Singphos, Khamptis, and Burmans only used tea prepared in a particular way, that is pickled tea, but I find that they take our tea prepared in the ordinary way. I will not lose sight of this matter. A little encouragement may lead to a fair amount of trade. I do not think any of this tea purchased by Kaiyas from ryots is exported to other districts or to Calcutta. It all appears to go to the hills in the direction of the Hukong Valley."—*Indian Planters' Gazette.*

COCONUT PLANTING IN CEYLON,

Of all investments in Ceylon, none have from "find to finish" shown such good results as coconut planting. The profits have never, perhaps, been so great as to lead to "booms" and other means of self-deception. A coconut property once in bearing need never be worked to a loss, and if of sufficient area, must always leave a profit. As far as Europeans are concerned, plantations have seldom been large enough; anything under 500 acres of good, or 800 acres ordinary, is the lowest extent they should be, and if of greater area so much the better. In all cases they require protection; so the larger the area inside the more easy will it be to surround them with watchers. Then the systematic destruction of beetles and other pests, and the chief, perpetual work of coconut growth is provided for.

I should think that few investments would be safer and more certain of paying over a long period of years than coconuts. As far as my experience goes, fifty to a hundred years does not appear to affect their productiveness. Indeed, I doubt if trees exist which may be considered as gone out, or as having ceased to be productive through age.

I see from your paper that there is a possibility of a Coconut-growing and Trading Company starting in Ceylon. This should certainly be successful if carefully started and organized, and, above all, if it avoids small plantations, only going in for groups or those of large area, and, when purchased, has them well and economically managed. The soul of the coconut enterprise is economy. If, in combination with cultivation, oil mills and other machinery are put up for utilizing the hundred-and-one uses to which the palm can be applied, with care and good judgment it should be the best spec Ceylon has ever seen, and an enterprise which Government and the public should encourage in every way. There is not the apparent margin in coconuts that exists in speculative products; yet all who have had to do with them, as well as with cinnamon, coffee, tea, or cocoa, know that while the latter products appear better than they are, coconuts at the long run come in at a canter. Indeed, there is a safety in them which makes the enterprise something more like Consols or Government Securities rather than the usual form of tropical agriculture.

The Company in prospect would, however, I presume, having mills and other means at their disposal, save much of the loss to producer which now falls into the hands of the middleman, shipper, and consignee in the European markets. All considered, I know no enterprise more likely to commend itself to that portion of the public who desire the elements of safety and permanent success rather than a flutter of high profits, consequent strong competition, and finally a fall to more normal profits, as seems to be the natural and logical result of touching anything nowadays with prospects of that quality which may be pronounced too good to last. Experience should teach the world to consider that permanence is of more value than temporary great results, and if from the beginning this is realized, with proper management, care, and economy, a real and steadfast industry may be started.

Like all other investments of the same nature, care will have to be taken in purchasing; for a very large proportion of the early opened plantations were badly planted, and have struggled through difficulties which only a coconut could survive, and only a believer in "Nirvana" would subject it to. It is needless to say that such properties are never likely to compete with those which from the first have had care; selected nuts in their nurseries; the jungle kept down around them; and have from the first been protected from beetles and cattle. I need hardly say the latter are what will in the long run prove the most satisfactory to purchase, and should go on for years with inexpensive cultivation. It is, however, an enterprise that should be undertaken on a somewhat large scale.

Veyangoda 17th March.

This is the most favourable first quarter of the year that I can remember, and stands out in striking contrast to the same period of the last year. We have not had a drought to speak of, and vegetation is revelling in the alternations of bright sunshine and refreshing showers we have had this month. Coconut trees have given up their yellow, faded foliage, for that of a healthy, dark green; the ground is green everywhere with fresh, tender herbage; and the Cinnamon bushes are actually laughing in the varicoloured garb of a leaf-bud. The talk of the hour in the villages is the ploughing of the fields for the *yala* crop, an operation that was not possible during this season for the last few years.

The language of exaggeration does more harm than good to a cause, and it was with regret that I saw a communication in the *Observer* on salt for the Coconut, whose thoughtless language is likely to damage a cause which Planters should have much at heart. In the communication under notice, it was asserted that an application of salt to a few scraggy coconut

trees was followed in a few weeks by luxuriant foliage and magnificent blossoms. Those with experience know that it takes many months before an application of manure shows any appreciable effect on Coconut trees. Is it possible that the case was different with so soluble and easily assimilable a substance as salt? Not likely, at least as regards foliage. I have noticed this slowness of displaying results with regret, especially at the present time in connection with the effect of the refreshing rains on the leaf disease. To me, not the slightest effect is perceptible on the affected trees, for there stand the punctured and semi-scorched leaves in all their hideousness, while new foliage is made at the usual slow rate. I cannot say that there is an abatement of the disease, for I constantly set fresh spots on plants not previously affected. It may be that my powers of observation have been whetted since my acquaintance with this new disease, but I certainly observed for the first time the tops of croton plants quite shrivelled up and covered with fungus. Cinnamon leaves too at intervals are met with, with spots like rust on them, and close examination on their undersides discloses fungus attacks.

The discussion on the causes that influence Cochil oil fetching a higher price than our own was at the outset interesting; it is now amusing. The child-like simplicity with which points that are in dispute are taken as proved is refreshing. Again, the climate of Malabar is said to be similar to that of Ceylon. We know that the climate of Ceylon is not uniform and the rainfall varies from 33 inches at Manaar to over 200 inches annually at some of the hill stations, while even along the coast the climate is not uniform. From a little north of Chilaw to the extreme north of the Island on the Western coast, and from beyond Tangalla to below Batticaloa on the Eastern coast there lie strips of land that are very arid with a rainfall of under 50 inches per annum, while there is a strip with Kalutara as the centre extending about 20 miles on either side of it with a rainfall of over 100 inches per annum. So that to tell us that the climate of Malabar is like that of Ceylon is to tell us nothing. Where Coconuts are grown along the arid coast of Ceylon, there copra of a superior quality is made which fetches high prices. Where the rainfall is pretty free as in the inland districts, and from about Negombo to Galle, good copra can be made only during the dry months; but the copra of dry districts always tops the market, not from any difference in the time of plucking of the nuts, but from its being uniformly cleaner. The gathering of even the products of the tree for fuel cannot be done for nothing, and then there is the cost of transport of the fuel and the loss to the soil of being robbed of some of its products which usually are allowed to decay where they fall, or are burnt there and the ashes returned to the soil. The "little care" that is wanted to watch the fires say for a couple months costs money, as also the stoking. No, no; practical Planters know that the cost of drying Coconuts in the husk is prohibitory, while as to its practicability with a crop of over 100,000, why the idea is ridiculous, however well it may answer for a few hundred Coconuts. Peasant proprietors can do it, but large Estates never.

Veyangoda, 17th June.

Speaking of crops reminds me that the cry on all sides is that this year's Coconut crops are shorter than those of last year, even where high cultivation is persistently carried on. This is due entirely to the two disastrous droughts of last year, separated as they were by only a couple of months. Leaf-disease too has been looked upon as the outcome of last year's abnormal weather. It was authoritatively stated that this malady was confined almost exclusively to regions where proper cultivation was not practised, and it was repeated more than once that Estates that were highly and intelligently cultivated escaped scathless. During a recent visit to Negombo, I had ocular proof that these repeated assertions were not founded on fact. On all sides, I saw the disease with which I have become familiar and bug also. The most that

can be said of the Estates of which I had but a passing glance is that they have not the disease in as aggravated a form as the Estates further inland have, but to say that they enjoy perfect immunity is "unmitigated bosh."

What a field for intelligent study there is in the thickly planted groves of coconut trees in the town of Negombo. For crooked stems commend me to them. The struggle for "more light" has been very great, and the stems present wonderful contortions. All accepted ideas of coconut cultivation and of the general principles of Agriculture are set at naught by the splendid trees in this prosperous town. A clear space of from between 25 to 30 feet is said by all authorities on coconut cultivation to be essential to the proper cultivation of coconuts. I saw trees planted so close as ten feet apart, not simply growing, but growing luxuriantly and bearing heavily. In his Report to Government on Coconut leaf disease, Mr. Driberg advises deep draining for Coconut Estates. This is in accordance with the fundamental teachings of Agricultural Chemistry, which by the way he will learn, as he gains more local experience, are not of universal application. Many parts of the town of Negombo are very low-lying, and a walk along its numerous minor roads will reveal to the observant visitor Coconut trees flourishing in garrens where the level of the water is within a couple of feet of the surface. A puddle here and a shallow trench there made for soaking coconut leaves before plaiting shows how very near the surface the water lies. In what seems a dead level there is perceptibly no fall for the water to drain away, and to all appearances it is stagnant, and yet the coconut trees growing on these lands have as dark-coloured foliage and as good crops as those growing on more favourable localities. The Cinnamon Gardens at Colombo present, in many parts, an almost exact counterpart of the conditions under which coconut trees flourish at Negombo. Deep-draining is said to be synonymous with deep cultivation, and deep cultivation is necessary to allow the roots to go down deep into the soil and be away from the regions affected by droughts, and also to favour a thorough aeration of the soil with all its concomitant benefits. I can show anyone a Coconut Estate of over 50 years composed mostly of a hard, and to all appearance, impervious soil, that has never been manured, nor the surface disturbed in any way, that has no drains on it, and yet is bearing crops that will put to shame younger Estates and in more favourable localities. And this too in a district which, according to a sapient correspondent of the *Observer*, has slab rock below the surface, and according to another as sapient authority has a dry climate and a hard soil peculiarly affected by droughts. I hope in what I have written not to be misunderstood, and to be thought to underrate the value and the benefits of draining, tilling and manuring. I have simply mentioned the different conditions under which Coconut trees are found to flourish, and which apparently seem to upset the teachings of Agricultural Chemistry founded on careful and long continued experiments carried on by some of the highest authorities of the present day. They present problems which laymen cannot solve, and which ought to engage the attention of professionals.—Local "Examiner."

CEYLON TEA ON THE CONTINENT.—Mr. John Fraser, while in Carlsbad, took the opportunity of seeking to spread a knowledge of our new staple. The *Karlsbader Badeblatt* of 16th June contains an advertisement, of which the following is a translation:—

Ceylon Tea.

Mr. Fraser, tea planter from Ceylon, who is at present staying here for the cure, would be very willing to give information on the character of the famous Ceylon tea, and at the same time enter into negotiations with those who may wish to import genuine Ceylon tea into this neighbourhood. Parkstrasse, "Prinz Eugen," Carlsbad.

COTTON IN THE MATALE DISTRICT.—We are glad to learn that some 300 to 400 lb. cotton seed have been distributed among the natives of this district, and Mr. Burrows will probably give out as much more before the end of the year. When the people find out that they can sell their crop—whether it be one of few or many lb.—to the Company's representative for cash on the spot, they are certain to be encouraged to continue and extend the new enterprise. At present many of them do not understand what the 'Agent Mahatmaya' is after, in giving them seed: is this to be a new means of taxation, or of reintroducing rajakariya? Mr. Burrows will no doubt make their admission to the annual grand district tamasha, conditional on at least some cotton crop being forthcoming!

TEA CULTIVATION AND MANUFACTURE IN THE SHAN STATES.—The *Manchester Guardian* has been publishing extracts from private letters sent home by Mr. W. Sheriff of Rangoon, who has been making a journey through the North Shan States on behalf of the Rangoon Chamber of Commerce. In one of these letters Mr. Sheriff says:—

The Paloungs are peculiarly different from the dominant race of Shans in every way. As previously stated, their livelihood is chiefly by growing tea, the mountain slopes being covered by tea plantations. Their way of curing and preparing the tea is very primitive, the sun doing the work principally. The tea, however, has a high value with the Burmese on account of its bitter taste, and the industry is a flourishing one. A large quantity is sold as "wet tea" or pickled—a sloppy sort of paste much admired as a delicacy in Burma, which appears to attain its highest flavour by being kept decomposing in a hole in the ground for six months or longer.

If this is the kind of tea that the Burmese appreciate, we fear that Ceylon tea would be scarcely 'flavory' enough for their palates. Commenting on these letters the *Rangoon Gazette* says:—

One thing seems certain, that China is likely to find in Upper Burmah and tributary States a new competitor in the tea trade.

Poor China! This would be the last straw. She had better begin to set her house in order.

SLAVE EMANCIPATION IN BRAZIL was thus referred to in the Emperor's speech opening the Session of the Legislature:—

By virtue of the civil emancipation which you decreed in the last session, the substitution of labor is proceeding fairly, without those profound shocks which have everywhere followed crises of this character. The agricultural class has understood that property would become useless and valueless, when no longer productive of income, and resolutely inaugurated the new régime, from which is to arise the regeneration and augmentation of industries. The Government has assisted, in so far as you had granted it means, this movement of economical and social transformation. It has, therefore, used all endeavour to extend the railway system, whether by authorizing the extension of lines belonging to the state, or by granting interest guarantees to such as, under advantageous conditions, can be built by private enterprise. The high powers of the state have not been less solicitous in aiding agriculture and other industries, assisting the current of immigration, already voluminous, and in great part spontaneous, as exemplified by the prosperity of the foreigners that seek our country. The arrivals in the past year reached 131,000 immigrants; and recent months show an increase. To strengthen immigration and improve agricultural labor it is necessary that, as your wisdom shall decide, the project to regulate territorial property and facilitate the acquisition of abandoned lands, should become law. Upon such occasion you can decide as to the property of granting to the Government the right to condemn for public use and land bounding on the railways, which is not cultivated by the owners and may be available for colonial nuclei.—*Rio News.*

NERIUM OLEANDER.*

The bark of the *Nerium oleander* contains a glucoside Oleandrine, which has lately been investigated, and found to have a powerful action upon the heart, not unlike that of Strophanthin and Digitaline. The results published go to prove that it is a very active poison, deriving its properties from several ingredients. In cases of asystole due to renal or cardiac lesions, it acts as a tonic to the heart, and increases diuresis, and would appear to be useful in those cases in which Strophanthus may be used, but the information is not yet completed on these points. It does not accumulate in the system. The preparations used are:—The Hydro-Alcoholic Extract in doses of $\frac{1}{3}$ rd grain per diem, gradually and cautiously increased to two grains; the Tincture, representing 1 part of the bark to 5 parts of alcohol, in doses of 5 to 10 drops per diem.

I am informed that Oleandrine is not obtainable in a pure crystalline form, such as would render it conveniently and easily handled for medicinal purposes.—*Christy's New Commercial Plants and Drugs.*

EUCALYPTUS HONEY.

In May, 1884, Mr. E. Guilmeth, a distinguished French naturalist, during his travels in Australia, noticed at the summit of one of the Eucalypts a curious formation, which greatly puzzled him. Thinking he had discovered some gigantic gall he made as careful an examination of it as he could with a field-glass; after spending some time in this way, heard a gradually increasing buzzing, and saw thousands of black insects, smaller than the bees of this country, hovering round an aperture in what he had thought to be a gall. He at once concluded that it was a hive, and that the bees were of a family hitherto unknown to him. Being desirous of possessing the hive, he gave orders to his followers to cut down the tree, and while this was being done he retired to a spot whence he could watch the movements of the bees. He was much surprised to see some of the bees fly to within a few yards of the workmen and return rapidly to the hive, evidently, in his opinion, playing the part of scouts; as soon as one lot had returned to the hive, another came down to return as quickly, and so on till the work of cutting down the tree was accomplished. The measurement of this Eucalypt was 7 metres diameter, and about 80 metres in height; Before pulling it to the ground the men were carefully protected on the hands and face, so that when it fell the bees swarmed round them without any serious effect. The Queen was soon induced to leave the hive and with her went her subjects. Mr. Guilmeth then tasted of the honey, and found it to possess all the flavour of the Eucalyptus essences; this discovery was so important that he collected a supply of the honey and forwarded it to Dr. Ch. Thomas-Caraman, of Forges-les-Eaux, in Normandy, for examination, who presented a paper on the subject to the Academy of Medicine in Paris, in January, 1887.

Specimens of the bees were shown, and as in no books of reference any trace could be found of this bee, it was named *Apis nigra mellifica*. The bee is small and quite black, with a trunk appearing much more developed than in the bees of France or Algeria. It is interesting to note that Mr. Guilmeth tried, without success, to acclimatise this bee in Tasmania; also, that experiments were made in Algeria to get the bees there to take to the Eucalyptus flower, but with no better success. It is well known that Narbonne honey owes its peculiar flavour to the rosemary which abounds in the neighbourhood, and that that of Mount Hymettus is due to the Labiates. It was, therefore, thought that the domestic bee might be made to frequent the Eucalyptus flower and leaf, and thus a supply of this valuable honey be obtained such was not the case, as the bees gradually died off.

Eucalyptus Honey is not an artificial product, but a pure honey containing, as will be seen from the following analysis made by Mr. Ch. Herisson, Director of the Chevrier Laboratory in Paris, all the valuable

principles found in the Eucalyptus tree, and to the presence of which are due all its wonderful antiseptic and anti-malarial properties.

Sugar (mostly lævulose)	—	—	611.6
Ash	—	—	1.8
Moisture	—	—	215.6
Active principles, i. e., Eucalyptol, Eucalyptene, terpene, cymol, colouring, resinous and aromatic principles	—	—	171.0

1000.0

Its rotary power in polarized light was 22° and its density 1.44.

A glance at the above figures will at once establish the great importance of this honey as a nutriment and as a therapeutic product.

Various experiments were made by Mr. Herisson to artificially obtain this honey by mixing the various ingredients together with ordinary honey, but it was found that no amount of careful stirring and other treatment would prevent the active principles from separating and gradually volatilizing. Eucalyptus Honey filtered at a temperature of 68° Fahr., presents the appearance of a thick transparent and homogenous syrup, of a deep orange colour, with an odour which at once points to its source. It is very soluble in water, milk, and wine, but less in alcohol; it is difficult to ferment, on account of the large proportion of sugar which it contains.

Dr. Thomas-Caraman gave some of the honey in warm milk to dogs, upon which it produced slowing of the heart's action, and a surprising diminution in the pulsations: in a small dog, from 124 to even as low as 70 per minute, the temperature being reduced by 1°. These effects lasted about 24 hours, and were accompanied by drowsiness, but without toxic depression. Upon himself, the Doctor found it, if taken in warm milk, to yield a most pleasant beverage, and to produce, after a few minutes, an agreeable sensation of warmth throughout the body,* the active principles of the honey being eliminated through the larynx and the bronchial tubes, rendering the voice clearer and more resonant; breath became perfumed, and the lungs acted in a freer and more elastic manner. After taking the honey for a week, the Doctor said he could take violent exercise without any strain being felt.

Eucalyptus Honey, with its 612 parts, per thousand, of pure sugar, will take a leading place amongst nutriment; it will prove an important substitute for Cod Liver Oil, in cases of bronchitis, phthisis, scrofula, &c.; while, as a sedative to the heart, as a febrifuge, as an antiseptic and antiparasitic it would appear to be second to no other product.

Its action upon the function of the bronchial and pulmonary passages is to regulate them, and to reduce catarrhs; while on the heart it acts in a similar manner to digitalis.

Without going further into the uses to which Eucalyptus Honey may be put as a simple and enjoyable remedy, we may state that the uses of its active principles are: EUCALYPTOL, in intermittent fevers, post-scarlatinal nephritis, albuminaria coughs, and as a tonic, stimulant and antiseptic. EUCALYPTENE, the tonic bitter and amorphous principle of the Oil of Eucalyptus, used in malarial fevers. TERPENE, a powerful antiseptic, disinfectant and deodoriser, used in phthisis, dysentery, and to prevent intestinal infection. CYMOL, a stomachic and carminative.

Eucalyptus Honey is designed to play an important part in the treatment of laryngeal, bronchial, pulmonary, cardiac and scrofulous affections; in malarial and typhoid fevers; in whooping cough and influenza; in diseases of the bladder and kidneys; and in catarrhs.—*Christy's New Commercial Plants and Drugs.*

NATIVE INDUSTRIES: NUTMEG—COTTON—PADDY.

There was some attention paid lately in your columns regarding the cultivation of nutmegs more particularly as a suitable industry for villagers. It is not beyond the means of the poorest cultivator who got

* It ought to be tried for chilblains, and cold hands and feet.

* The natives believe that the strong smell of this beautiful flower is poisonous.—Ed.

a patch of land to plant a few of these trees at least in a compound. I have seen these trees thriving well in several compounds, and two or three trees which I saw growing in some villages near about have an abundance of fruit. The annual produce of a tree could be estimated at something over two thousand fruits. But it cannot be said whether it will produce the same quantity if planted in a large area. A tree at the rate mentioned would yield the owner at least ten rupees a year, which is no trifle for a poor cultivator. But in spite of what they see in their neighbours, the goyias do not care to grow these at all. The question why they do not grow it comes before us. It cannot be their laziness, as a nutmeg tree does not require much labour; then is it their apathy which prevents their doing this? Though the goyias are often accused of apathy I don't think they deserve it to such an extent. It is only ignorance and carelessness produced by want of a proper market at hand. If they could be made to see that it will bring money to them they are sure to grow it. For instance in the case of a villager it is very seldom we require any inducing to make them grow coconuts. He knows fully well that if he plants it he will either get the value or be able to use it himself.

Therefore to induce a villager to grow any new product one should be ready to show them a market, and this coupled with the example of their neighbours and a little rousing up as it were by force from the proper authorities is I think the whole key to native industries; without either of these it is next to impossible to make them move a single step. Though the above remarks are made under nutmeg it would be well to consider whether the industries which have ceased and which are existing have been and are governed by the same causes. For instance it is said that cotton was grown in Ceylon for industrial purposes, and it ceased because the machine was not fed up with a ready market. In those days there was a market opened to the cultivators for supplying the article for native looms. With the introduction of Manchester goods the working of the looms stopped and the cotton industry too succumbed with it. This and other instances in regard to different industries points out clearly that a demand at hand is one of the great requisites for promoting native industries. The Directors of the Spinning Company have hit upon this principle and have established agencies in different places in the island for buying up the produce, and this would no doubt go a great deal in promoting this industry.

There is much talk at the present moment whether the cultivation of paddy is paying. Carefully compiled figures and statistics, taking an average crop into account (and not a bad one) have shown that it is a paying investment. There is no doubt that there are some fields which would not pay the ordinary cultivator. But such cases are very rare. Your extract in the June *Tropical Agriculturist* on the cultivation of rice in Guiana is a very interesting one, and there is much in it for us in Ceylon to think of. The African cooly and the Indian immigrant all adopt the transplanting system, and broadcast sowing is not known amongst them. But our goyias in Ceylon stick to the wasteful system of sowing broadcast, wasteful on two accounts: first, in the amount of seed paddy, and secondly, in the crop obtained. In some villages the cultivators pay 100 per cent interest on the seed paddy they borrow, and in some seasons they leave off whole tracts of land uncultivated for want of seed paddy.

Another great advantage which is of no little consequence to be derived from a system of transplanting is the prevention to a great extent of damages by floods. Generally plants when very young suffer much from high water, but the damage on those which are planted out would be very little. W. A. D. S.

TOBACCO PLANTING IN BORNEO.

The Borneo S. S. Co.'s steamer "Paknam" now in port, has brought 92 bales of tobacco from the See gannan Estate of the Tobacco Company of British-North Borneo, of which Mr. George Stephens is Manager. This first crop has been grown by a mere handful of coolies amidst the usual difficulties of opening up a new estate, and the result promises very well for

the future of this plantation, where tobacco is now being grown on a large scale. "Paknam" during the two previous voyages brought up about 600 bales from the Ranow estate of the Count de Gelees, one of the most successful of North Borneo planters, and to whom the country owes a great deal. The "Benmore," of the same line, also brought up 50 bales from another estate, and further shipments have been made by "blue funnel" boats. The prospects of nearly all the estates are most encouraging, and the initial difficulties having been fairly well overcome by this time, it may be reasonably expected that the different plantations will now make rapid progress.—*Straits Times*, 7th August.

NOTES ABOUT TEA AND THE TEA FUND.

(From an Upcountry Correspondent.)

Our Melbourne Agent, Mr. Hugh Mackenzie, has carried out his arrangements in a businesslike and creditable manner.

Dr. Duke's scheme is coming to the front again now that the American Tea Company has been floated. It ought to be supported by the Tea Fund and more especially the American Company, as it will much benefit the latter. It must be worked in a very complete and large-handed manner, through the length and breadth of America—at one time. If it leads to a lot of controversy in the papers on the part of our China and Japan friends, all the better. The more we are before the public the better. We have a really good article for sale, so publicity and controversy will be exactly what we want.

The question of analysis of our made teas came up at the Nuwara Eliya meeting, but no doubt there was not the time available to ventilate all that had to be said on the matter, *i. e.* whether the analyses should be made in London or Ceylon. This will no doubt be settled at the next Committee meeting which I trust will be better attended. I understand the Directors' meeting of the Ceylon Planters' American Tea Company had some important business before it. Outsiders wonder if Philip in Kandy as Secretary with a first-class firm in Colombo as the agents of the Company would not have done the job as economically as the present team who run the concern. Time will show. No doubt, Mr. Grinlinton and Darley, Butler & Co. have the confidence and rightly so of business men, but it does seem hard that Mr. Philip who endured the burden and most of the initiating proceedings should have lost the business when the plum was ripe. Such is life in a tropical climate. Pineo and his manservant and maidservant starting to run the tea campaign in the Continent of America has its amusing aspect—but the II. Napoleon first stormed Boulogne with his tame eagles; Disraeli was the subject of ridicule when he made his speech in the House of Commons; and Pineo and his pair of colored doves are doubtless the brave Pioneers of the great battle of Ceylon Tea *vs.* China and Japan that will soon be fought in that vast Continent.

SO MORE IT BE.

[Is it not clear that the American Tea Company would not have floated without the aid of Colombo men who made it a condition that the business should all be conducted down here; no reflection on worthy Mr. Philip in that—it was simply a question of location and we suppose the meeting decided in favour of Colombo.—ED.]

COMPARATIVE COST OF BRITISH AND FOREIGN PATENTS.

The *London Chamber of Commerce Journal* furnishes the following table showing the costs incidental to procuring and maintaining patents for the full term permissible in the principal countries in Europe, Asia, Africa, North and South America. The term of the

patent and the average cost per annum, assuming the patent to be maintained for the full term, are thus stated:—

Country.	Term. Yrs.	Office Fees.			Average Cost per annum		
		£	s	d	£	s	d
Great Britain	14	154	0	0	11	0	0
France ...	15	60	0	0	4	0	0
Belgium ...	20	84	0	0	4	4	0
Germany ...	15	264	0	0	17	12	0
Austria Hungary	15	73	10	0	4	18	0
Italy ...	15	60	0	0	4	0	0
Spain ...	20	84	0	0	4	4	0
Russia ...	10 about	50	0	0	5	0	0
British India	14	52	13	0	3	15	3
Cape Colony	14	87	4	6	2	13	2
United States	17	7	3	6	0	8	5
Canada ...	15	12	6	0	0	16	5
Argentine Republic	15	71	15	0	4	15	8
Brazil ...	15 about	160	0	0	10	13	4

Average 15.3 83 12 0 5 10 5

From the above table it will be perceived that the average term of a patent-grant in the foreign countries named is 15.3 years as against 14 in Great Britain; that the average total cost is £83 12s, as compared with £154; and that the average annual cost is £5 10s 5d, or about one-half that of a British patent if maintained for the full term.—*Ceylon Advertiser.*

ANALYSES OF CEYLON TEA, AT THE MELBOURNE EXHIBITION OF 1880-81 AND SUBSEQUENTLY.

Colombo, Aug. 17th, 1889.

To the Standing Committee of the Ceylon Tea Fund; per favour of the *Ceylon Observer*,

GENTLEMEN,—In the report of your meeting held at Nuwara Eliya on 9th instant, published in the *Observer* of the 14th appeared the following paragraph:—

“ANALYSES OF MADE TEA FROM THE VARIOUS DISTRICTS OF CEYLON.—Resolved that consideration of this subject be deferred, and that Mr. A. M. Ferguson Senior be asked if he had analyses of Ceylon tea made in Australia when as Commissioner he represented Ceylon at the Melbourne Exhibition of 1880.” Nothing can more strikingly prove the rapidity with which even comparatively important matters fade from the public memory, than that such a question should arise at a meeting composed of some of the principal planters in Ceylon (who were here in 1880-81) and including Mr. C. S. Armstrong! Of all the services I have rendered to Ceylon during nearly fifty-two years of residence and labour on behalf of the island's interests, I felt and still feel justified in regarding my successful efforts to establish the high character of Ceylon tea, by obtaining the opinions of experts and the careful and numerous analyses (nearly 80 in number) of the teas sent to the Melbourne Exhibition of 1880-81 under my care as Commissioner, as one of the most important and the least likely to be forgotten,—at any rate by Ceylon tea planters. I first obtained and published the opinions of most competent tea tasters:—Indian (Sibthorp); Australian (Moody); and English (Brown). I next secured analyses of the most extended and careful character, by such chemists as Mr. Cosmo Newbery, C.M.G., and his assistant, Mr. Dunn. In forwarding to Ceylon the results of those analyses, I accompanied them with an elaborate report in which numerous comparisons were instituted between our teas and those of India and China as examined by the same analysts. The general results were that the Ceylon teas took rank by the proportion of ash (under 5 per cent) as the purest in the world, while the average quantity of total extract was such as had hitherto been unprecedented. The average figures of the exceedingly

favourable analyses and my report thereon, with which I took special pains, and also the report of Messrs. Henty & Co., and the opinions of the chemists and experts, were published in the *Observer* at the time, and you will find them repeated in ample detail in the 1881-82 volume of the *Tropical Agriculturist*, pp. 197-214.

It will be for your Committee to decide whether portions of the information contained in these and other pages of the periodical referred to might not with advantage, be now reprinted for distribution in America and elsewhere. Beside the early and very important Melbourne analyses, it has fallen to me to notice many others, and especially very valuable analyses by Mr. Cochran of green leaves, that is of leaves in their natural state as gathered from the tea tree. I also commented on the same gentleman's recent analyses of Roseneath tea, which at an interval of over eight years showed that Ceylon teas still retained their high character for special purity. To Mr. Cochran tea planters were also indebted for the publication here of analyses of Indian teas made at different seasons, which proved that teas grown in the warmer summer months showed great superiority in quality. In a recent volume of the *Tropical Agriculturist* will also be found Dr. Paul's interesting analyses of Ceylon teas with reference to proportion of theine in connection with altitude, my comments on which drew from the eminent chemist a request to be furnished with an extensive series of specimens of Ceylon teas, grown at all altitudes, for examination. It will be quite within the functions of your body, and I feel sure it will give you pleasure to do for Dr. Paul that which individually I could not accomplish. In truth a pamphlet of interesting and valuable matter on the character and constituents of our fine and pure teas could at this juncture be profitably compiled from the *Tropical Agriculturist*. I have added so much to the affirmative answer with which I anticipate a question that has as yet reached me only through the *Observer*.* Through that medium I reply, because I should not wish the public to share for a longer period than can be helped the doubt which so strangely actuated the Committee. Alas for the memory of what I flattered myself was one of the greatest services I had ever done to Ceylon, in aiding so materially (according to the verdict of competent judges) its then young and struggling tea enterprise!—I am, gentlemen, yours truly,
A. M. FERGUSON.

P. S.—An extract from my comments on the results of the numerous and careful analyses which

* Aug. 19th.—The official letter, dated 17th, forwarding the resolution reached me only this morning, and I have replied by referring to tomorrow's *Observer* of which a copy will be forwarded to the Secretary. The letter is as follows:—

Kandy, 17th August 1889.

To A. M. Ferguson, Esq., C. M. G., Colombo.

Sir,—“Analyses of Made Tea from Various Districts.”—With reference to the abovenamed subject, which was brought up for discussion before the Standing Committee of the “Ceylon Tea Fund,” at a recent meeting, I beg to annex copy of a resolution passed by the Committee, and to ask if you will kindly favour me with a reply to the question asked therein?—I am, sir, your obedient servant.

A. PHILIP, Secretary.

RESOLUTION REFERRED TO.

Resolved:—“That consideration of this subject be deferred, and that Mr. A. M. Ferguson senior be asked if he had analyses of Ceylon tea made in Australia when as Commissioner he represented Ceylon at the Melbourne Exhibition of 1880.”

I got made by the highest scientific authorities in Melbourne in 1880 will show how very important and favourable to the character of Ceylon teas those results were, at a time when London brokers persisted in decrying our new product:—

Melbourne, Dec. 9th, 1880.

I have received the analyses of Ceylon teas exhibited, made by Mr. Dunn of the Technological Department, under the supervision of Mr. Cosmo Newbery. As I wrote before, the analyses represent averages, pekoes, souchongs and so forth, the exceptions being those in which only one specimen was shewn. I got a copy of Mr. Dunn's report at Messrs. Jas. Henty & Co.'s office last evening, with a promise from Mr. Moody that his remarks would reach me early this morning. The paper is not yet to hand, but I know what its general purport will be, in consequence of a long conversation I had with Mr. Dunn and Mr. Moody respecting the results obtained, some of which are extraordinary, and in the case of the proportion of mineral ash anomalous. As noticed previously, the British analysts' standard for mineral ash in tea ranges from 5 to 8 per cent. So it is recorded in Mr. Newbery's office; but, as I told you previously, the result of my own rather extensive reading on the subject led me to believe that the standard for genuine tea was 5 to 6 per cent, and that any excess over 6 per cent must be due to the mixture of foreign substances, from careless preparation and packing, or from designed adulteration. On the other hand, a percentage of ash much lower than 5 per cent would at once raise the suspicion in an analyst's mind that he was dealing with washed-out leaves. Mr. Dunn's analyses of our Ceylon teas present the contrasts of the lowest proportions of mineral ash and the largest of that extract for which tea leaves are valued, ever obtained. Mr. Dunn, as a chemist, felt bound to offer such explanation of the anomaly as seemed to his mind most satisfactory, and you will observe that he adduces as a probable cause the rapid growth of the tea plant in Ceylon. That he correctly judged (apart from clean and careful preparation) I have strong proof in the independent judgment of my esteemed friend, Mr. Josiah Mitchell, one of the best authorities on the science of agriculture in Australia. He came here (to his brother's house, where I now reside) last evening, and I stated to him the curious results obtained by Mr. Dunn, without mentioning that gentleman's solution of the apparent anomaly of minimum mineral ash and maximum extract. Mr. Mitchell at once said:—"I congratulate you on results which ought to be deemed satisfactory to all interested in tea planting in Ceylon. The proportions of extract, soluble salts and theine to mineral ash prove that the influence of your climate is such that of the mineral matter taken by the plant from the soil all but a very small quantity is elaborated into the properties which make tea leaves valuable for consumption and commerce. The result of the analyses proves that in Ceylon the best quality of tea can be produced with the minimum exhaustion of the fertilizing matters in the soil." If, as I believe, this is the true solution of the results of Mr. Dunn's analyses, I think that you and the Committee,* the Government, the planters and the merchants of Ceylon, will feel that here alone is compensation for the expense involved in being specially represented at this important Exhibition. Both Messrs. Dunn and Mitchell (especially the former) were deeply interested in information I gave them of the different conditions under which tea was grown in Ceylon and in most of the tea districts of India and China. In Ceylon, I pointed out, tea is grown within 7° of the Equator, while the vast majority of the gardens of India are situated 20° farther north. In the case of Darjeeling, leaving the Terai and Doonars out of view, the factor of altitude has to be added to latitude. Some tea is grown on the Nilgiris and in a few other districts in Southern India, about 11° north, but the vast bulk of the teas which India (and I may add China) sends into the markets of the world are grown between 20° or 30°, some even as far as 34° north latitude.

* Mr. Bruce and the Ceylon Exhibition Committee.—A. M. F.

The result is that the plant gets a "wintering"—there is a stoppage of growth from November (in which month, in India, pruning generally severe, is performed) to March. At the commencement of the tea-planting enterprise in Ceylon, Indian tea planters predicted failure from the absence of winter in our island—from the constantly forcing nature of the climate. As to quantity per acre, a comparison with Assam cannot yet be instituted on a large scale, but I submit that these Melbourne analyses, added to the tests as tea-tasters applied by Messrs. Moody and Sibthorp, and the judgments delivered by them, conclusively prove that, in the hot, moist climate of Ceylon, tea can be produced which, if carefully prepared, will rank with or even above the finest quality sent into the markets of the world.

I add to the above short extract from a long letter, addressed to Mr. Bruce, the reports of the late Mr. Moody of Messrs. Henty & Co., and Mr. Dunn, the chemist, noting in regard to the latter that the "six samples of tea" analysed were mixtures of 78 separate teas of different classes exhibited in the Ceylon Court:—

MESSRS. JAS. HENTY & Co.'s LETTER ANENT MR. DUNN'S ANALYSES OF CEYLON TEAS.

Melbourne, 8th December 1880.

A. M. Ferguson, Esq., Commissioner for Ceylon, M.I.E.

Dear Sir,—We now hand you the report of Mr. F. Dunn, of the Government Laboratory, on the average samples of Ceylon teas handed to him for analysis, as advised in our last of 24th ulto.

The orange pekoe, pekoe, pekoe souchong and souchong are highly satisfactory, the percentage of extract being very large, of soluble salts full, which, with a low percentage of ash, stamps these teas as of the greatest purity.

Congou, which is usually considered the commonest tea, turns out very good for its class, the percentage of extract 37.40 being well over the standard of extract for lowest class genuine tea, say 30 f. c.

There being only two samples of green tea to show, it was hardly a fair average, but turns out very high for extract, soluble salts fair, but theine low. In green tea we look for a high percentage of theine and can only account for present result by the method of manufacturing, these two samples forming the average.

We think you have every reason to feel satisfied with the result of analysing the 78 samples in your Court, and which fully confirms the high opinion formed of your exhibits by Mr. Sibthorp and ourselves, and we leave you to judge of what the result would have been if only the best samples had been selected and sent in for analysis.—We remain, your obedient servants, JAS. HENTY & Co., per J. O. MOODY.

MR. DUNN'S ANALYSES OF CEYLON TEA.

Industrial and Technological Museum Laboratory,

December 8th, 1880.

Report on six samples of tea received from James Henty & Co.:—

Marks.	Name.	Per cent of ash	Per cent of extract.	Per cent of soluble salts.	Per cent of theine.
81	Orange Pekoe	4.60	44.80	3.06	2.15
82	Pekoe	4.92	43.80	3.32	1.82
83	Pekoe Souchong	5.04	42.80	3.12	1.86
84	Souchong	4.84	40.40	3.20	1.84
85	Congou	4.80	37.40	2.96	1.82
86	Green tea	4.72	41.00	2.66	0.94

The high percentage of extract, soluble salts and theine (with the exception of the congou and green tea) found by analysis, proves these teas to be of first-class quality.

The low percentage of mineral ash (which is generally between 5 and 6 per cent) may be accounted for (1) By the quick growth of the tea plant. (2) By the careful manner in which the leaves have been collected and sheltered from the dust, &c.

A low percentage of mineral ash is detrimental to the quality of a tea when the soluble salts fall in percentage (that is below 3 per cent.)

It would prove of scientific interest if a larger number of these teas were carefully analysed with especial reference to percentage of mineral ash.

FREDERIC DUNN.

THE COCONUT CRAB.

A very remarkable crustacean is now on view in the Zoological Gardens, Regent's-park, having been presented to the society by Commander Alfred Carpenter, R. N. It is the first specimen that has been received of the singular cocconut land crab, of which species closely resembling one another exist in many tropical countries, some of the specimens being natives of India, and others of tropical islands in the Pacific, &c. It has long been believed by the natives of the countries in which they are found that the robber crabs—the *Birgus* latro of zoologists—have been in the habit of climbing trees in order to steal the coconuts. Mr. Cuming, a very correct authority states that they do really climb up the trunks of a species of palm tree—the *Pandanus odoratissimus*—to obtain a small kind of coconut on which they feed. They live in excavations amongst the roots of the trees, and constitute a very favourite food of the natives of some districts, whilst in others they are credited by the inhabitants with digging down to the graves and eating the bodies, an accusation apparently without foundation. The legs are perfectly in accordance with the habits of the animals. The anterior are furnished with powerful claws, with which they pull off the fibrous covering of the shell of the nut at the end where the three eye like holes are situated; these are then opened, and the slender hinder claws employed to pull out the edible interior. Mr. Cuming further states that the deep holes in which the crabs live at the bases of the tree are lined with the fibre torn off the nuts. The claws placed between the anterior and posterior limbs have pointed extremities admirably adapted for the purpose of climbing the palm trees from which they obtain their food. The habits of a closely allied, if not identical, species are graphically described by Charles Darwin in that, to me, the most delightful of all journals, "A Naturalist's Voyage," which I value the more, as it was the first of very many books that the author gave me during our intercourse of more than a third of a century.

Mr. Darwin writes as follows regarding the species:—"I have before alluded to a crab which lives on the cocoa-nuts; it is very common on all parts of the dry land, and grows to a monstrous size; it is closely allied or indetical with the *Birgus* latro. The front pair of legs terminate in very strong and heavy pincers, and the last pair are fitted with others weaker and much narrower. It would at first be thought quite impossible for a crab to open a strong coconut covered with the husk; but Mr. Liesk assures me that he has repeatedly seen this effected. The crab begins by tearing the husk, fibre by fibre, and always from that end under which the three eye-holes are situated; when this is completed, the crab commences hammering with its heavy claws on one of the eye-holes till an opening is made. Then turning round its body, by the aid of its posterior and narrow pair of pincers, it extracts the white albuminous substance. I think this is as curious a case of instinct as ever I heard of, and likewise of adaptation in structure between two objects apparently so remote from each other in the scheme of nature as a crab and a coconut tree. The *Birgus* is diurnal in its habits; but every night it is said to pay a visit to the sea, no doubt for the purpose of moistening its branchiæ. The young are likewise hatched, and live for some time on the coast. These crabs inhabit deep burrows, which they hollow out beneath the roots of trees, and where they accumulate surprising quantities of the picked fibres of the coconut husk, on which they rest as on a bed. The Malays sometimes take advantage of this, and collect the fibrous mass to use as junk. These crabs are very good to eat; moreover under the tail of the larger ones there

is a great mass of fat, which, when melted, sometimes yields as much as a quart bottle full of liquid oil. It has been stated by some authors that the *Birgus* scrawls up the coconut tree for the purpose of stealing the nuts. I very much doubt the possibility of this; but with the *Pandanus* the task would be very much easier. I was told by Mr. Liesk that on these islands the *Birgus* lives only on the nuts which have fallen to the ground. Captain Moresby informs me that this crab inhabits the Chagos and Seychelle groups, but not the neighbouring Maldiva archipelago. It formerly abounded at Mauritius, but only a few small ones are now found there. In the Pacific this species, or one with closely-allied habits, is said to inhabit a single coral island north of the Society group. To show the wonderful strength of the front pair of pincers, I may mention that Captain Moresby confined one in a strong tin box which had held biscuits, the lid being secured with wire; but the crab turned down the edges and escaped. In turning down the edges it actually punched many small holes quite through the tin."

That the land crabs always deposit their spawn in the water is now well known, the eggs begin developed, not into young crabs, but into marine creatures of a very distinct larval form, known as the zoea. These swim about freely, and undergo a series of metamorphoses; as remarkable as those that insects undergo. The *Birgus* is for the present located in the tortoise-house, near the north entrance of the gardens. It should be visited by all naturalists, as it is one of those remarkable forms of animal life that would never be seen in England but for the opportunities afforded by the existence of these admirable gardens.—M. W. B. TEGEMEIER, in the *Field*. [This crab appears to be identical with that described more generally at page 200, vol. V (1885-6) of your *T. A.*—G. D. M.]

PLANTING IN LOWER PERAK IN 1888.

The padi crop throughout the district has been, on the whole, very good, and I hear of few, if any, complaints. I have under consideration a scheme, which has originated with a gentleman in Penang, to introduce Indian settlers to take up padi-planting on a large scale. Nothing definite has yet been arrived at, but the large, low-lying tract of land between the Perak and Bernam rivers is admirably suited for such a purpose, and would support a large population. It is to be hoped that the year 1889 will see a step taken in this direction.

The few Achinese pepper planters who were settled at Kruh have moved to Sungei Sitiawan. I am sorry to say that a fire broke out at Kruh, which seriously damaged the pepper trees, which had already suffered from a long drought. The Achinese have therefore joined their countrymen at Sungei Sitiawan, where they have taken up new land. The pepper plants at Sungei Sitiawan were inspected by His Excellency the Governor on the occasion of his last visit, and he was pleased to express his satisfaction at what he saw as to the growth and condition of the pepper planted. I am now trying to induce the Achinese to abandon the planting of the pepper cutting on dedap trees, and I have met with partial success. As they plant their pepper under dedap trees in their own country, it is not easy to induce them to change the system but they are gradually beginning to see its advantage.

Gutta cutting was resumed during the past year; this had not been permitted for some years past, with the hope of saving the trees, which had been almost entirely destroyed by indiscriminate felling. Felling was permitted, under certain conditions, and with a pass system, but the quantity supposed still to exist in the forests was over-rated, but sufficient gutta will be collected to recoup the towkays for the advances made.

An arrangement has been come to, under certain conditions, with a firm at Penang to invest a capital of \$20,000 in pepper cultivation, Government pro-

viding a like sum. This undertaking will be commenced probably on the Dindings; if so, it will confer a great benefit on the Kelantan settlers at Sungei Sitiawan.—*Perak Government Gazette.*

PROSPECTS OF DAIRYING IN CEYLON.

This is a subject which has been cropping up off and on in the local papers, and has been variously treated of. In conversation with landowners, I have been told that dairying—that is systematic dairying—will never succeed in Ceylon; that it will not pay to import milk cows at large prices; that such cows from England and Australia do not thrive as well as they do where they are native; in fact, that dairying has been tried and has not been a success. No doubt, it has not been a success, but only on account of the conditions under which the experiment has been tried. With the object of starting a dairy in Ceylon, there are two considerations to be noted—of what nature is our milking stock to be, and what is to be their food? That it will not pay to give large prices for foreign cattle, and that they will not come up to expectation, there is no doubt of. What should be done is that country cattle from stocks of fairly good milking qualities should be selected and the strain cultivated. The next thing is to provide the cows with nutritious and milk-producing food. Of course, it will not pay to cultivate turnips, even if we can get a decent crop in the hill country: but why should we not have good pasturage? Why should we not lay down permanent grasses? We trust to the common natural grasses to suffice, while with a little trouble we may have a good supply of nutritious grass food; and good grass is better than anything for milk cows. We have yet to make a complete classification of the best feeding grasses in Ceylon, owing to their properties not being sufficiently established by chemical analysis; but from observation we know that there are some which are better food than others, and why should we not select and sow them? The *atora* and *hariali* grasses are well known for their good feeding qualities. I have also been told that the grasses in the Island of Delft are peculiarly adapted for producing good stock. It suggested itself to my mind that it is not unlikely that some of the low-country grasses of England, which thrive in the South of France, would probably suit the hill country of Ceylon. In conversation with a gentleman who tried rye grass as an experiment, I learned that it should succeed very well. There is no reason why we should not use ensilage in the dry hot seasons when the grass is more or less "burnt up." Considering that there is a great deal of vegetation which cattle would not touch in the natural state (for instance, thistles and bracken in Scotland), but which they greedily devour as silage, and that the cost of erecting silage stacks (which is much cheaper than the old silo) is small, we could always have a supply of food for the slack seasons. Besides, silage is known to be splendid stuff for dairy cows. Of course, the hill country will have to be chosen for a dairy farm, as the temperature there is best suited for butter manufactory (putting aside cheese for the present.)

With the present prices for dairy produce and the demand for good stuff, there is no reason why a Dairy Supply Company, with headquarters in Colombo where all the produce should be sent, should not be a success.—*Local "Examiner."*

PARING AND BURNING VS. FUMIGATION.

To the Editor of the "Ceylon Examiner."

Dear Sir,—Your correspondent B. has already indicated, in his communication on "Fumigation," that the sources of his information on agricultural matters, and the fields of his observation are very limited. Here is a proof of what he says. In his article headed "Paring and Burning vs. Fumigation," he says that, as far as his information and personal observation go, Nuwara Eliya is the only place in the Island where the operation of Paring and Burnin on

clayey and peaty soils is regularly and systematically carried on. It seems B. has visited Nuwara Eliya, perhaps to shake off the dullness he felt by a long residence in "a sleepy hollow," as he calls it.

It will undoubtedly be very interesting, and perhaps surprising too, to B. to know that the operation of Paring and Burning on clayey and peaty soils has been carried on from time immemorial by our native goiyas. The oldest native goiyas will bear evidence to this fact. It is not a thing which has been taught to them by Europeans. It is regularly and systematically carried on even at present not only at Nuwara Eliya, as B. imagines, but also at most of the other places in the Island where lands having clayey and peaty soils are put under cultivation.

The native goiyas often resort to this operation for the preparation of land in the cultivation of paddy for "Kekulan" on clayey and peaty soils. Has B. heard of the popular Sinhalese agricultural expressions "Kekulan Kotanewa" and "Kekulan Pullussenewa"—the former means paring, and the latter burning, for Kekulan sowing?

Again, in speaking on "fumigation" B. says he has never worked in a laboratory and has never carried out scientifically conducted experiments—or in short, I might say, he never has had a scientific education. This is evident from his explanation of the composition of smoke given off by the burning of organic matter. He says that smoke is the moisture contained in a substance that is burnt passing off in the form of vapour, or in short that, it is steam or watery vapour. B. must learn that the smoke given off by the burning of organic matter is composed principally of unoxidised carbon atoms or soot, in addition to a little watery vapour &c., of course. A first lesson in chemistry would have taught him this. Does B. know the chemistry of the burning of a candle? If he conducts the smoke given off by the burning of organic matter or Carbon through a tube—a bamboo with the divisions knocked off will answer the purpose—and lights the smoke as it comes out at the other end, he will see that the smoke burns, proving that it is mainly composed of unburnt Carbon atoms. The denser the smoke, the greater is the amount of unoxidised Carbon atoms.

In an article on Salt written on the 15th April, B. says "Silica is a substance that stiffens all forms of vegetation." This was a very popular belief, but late experiments have tended to prove that stiffness does not depend on the presence of Silica in the soil.—Yours truly,
L.

LAST week we quoted some remarks on KAWRIE PINE from the *Timber Trades Journal*. Reverting to the subject in its issue of July 20th, our contemporary says:—"We are informed that the large logs of which we wrote have all been recently sold. Seeing them still in the sheds and knowing that they have been there since the middle of 1886, we naturally supposed them to be still on hand, and regret that we inadvertently made the mistake. We congratulate the brokers on having cleared them, and hope the buyer will find a ready market for them. It is rather a matter of surprise that Australian woods are not more pushed in this country. They have several advantages over the hard woods from colder climes, inasmuch as they are practically impervious to dry rot, and therefore well adapted for any work where it has to rest on bare ground. We understand a contract has been entered into for Jarrah in the formation of a wood-paved roadway, this description being required to form the gutter, or sidings. Instead of our Australian friends waiting for the trade to come to them, they should push their timber on the market here, and establish a demand, even if they have to be out of pocket at first. For wood paving, and any permanent roadway, better timber could not be found."—*E. Mail.*

EUCALYPTUS OIL of an exceptionally fine quality has been recently received from Adelaide, Australia. It is said to have been distilled from the leaves of *Eucalyptus odorata*, obtained from a Government forest of some 13,000 acres.—*Burgoyne's Export Prices Current*.

ARTIFICIAL COFFEE.—The Prussian Minister of industry has published an account from which it seems that the artificial coffee beans recently referred to consist principally of lupines, and contain about half per cent of caffeine, derived from a slight proportion of kola nuts. The husks contain a tannin and some resinous matter.—*Chemist and Druggist*.

LANTANINE.—This is an alkaloid discovered by Buiza & Negreta, of Lima, in the Yerba Sagrada (*Lantana brasiliensis*), one of the Verberna family. This alkaloid acts upon the circulation, retards the nutrition, and at the same time reduces the temperature; it is borne well by the weakest stomach. Two grammes of Lantanine are said to have cured intermittent fevers where Quinine failed. As an antipyretic 1 or 2 grammes in 10 centigramme pills are given in the twenty-four hours. In intermittent fever Lantanine should be given immediately after the paroxysm, and it is said that in 99 cases out of 100 the fever will not again appear. The tincture of the herb is so intensely bitter that it would be useless to prescribe it. These results have not as yet been confirmed in this country, as no raw material has been obtainable to enable the necessary experiments to be made.—*Christy's "New Commercial Plants and Drugs."*

MILES JOSEPH BERKELEY.—Full of years, rich in the respect and affection which a long life of singular manliness and almost unparalleled service to Science and Horticulture have most worthily won, Miles Berkeley died on the 30th ultimo at Sibbertoft, near Market Harborough, of which place he had been Vicar since 1868. Berkeley's eminence was gained in the field of Cryptogamic botany, and especially in the discrimination and description of fungi; but in almost all departments of botany and natural history his knowledge was both wide and deep, while his classical attainments were very considerable, and his general knowledge, as we have said, so encyclopaedic, that it is difficult to point to any subject of which he did not know something. His mind was eager and receptive almost to the last; it is only a few years since that we once found him busy in acquiring some knowledge of Polish, for the purpose of making himself acquainted with the results of some investigations made by Rostafinski and others. Miles Joseph Berkeley was born in the Parish of Oundle, Northamptonshire, in 1803. Mr. Berkeley was the first, and till quite recently, the only botanist in this country who devoted systematic attention to the diseases of plants; and his papers on vegetable pathology, which were commenced in these columns in 1854, and continued at intervals till 1857, still remain the most comprehensive of their kind in the language. In 1857 Berkeley published his *Introduction to Cryptogamic Botany*, which like his papers on Vegetable Pathology, occupied the field without a rival, till the recently published work of Messrs. Bennett & Murray, to which it will be our duty shortly to call attention. *Outlines of British Fungology* followed in 1860; and a work on *British Mosses* in 1863. In addition to these standard treatises, Berkeley was continually at work on the description of fungi from all parts of the world, often in conjunction with the late Mr. Broome, whose patient skill, judgment, and leisure were valuable aids to the more hardly pressed Berkeley. These continued labours were recognized by the scientific societies, who were proud to enrol so distinguished a naturalist among their Fellows. In 1863 the Royal Society did itself credit in conferring on Mr. Berkeley, not then a Fellow of that body, the greatest honour in its power to confer, viz., one of the Royal Medals. Major-General Berkeley, a son of the deceased gentleman, is known to many of our readers as an assiduous student of Orchids in Burmah and other parts of India.—*Gardener's Chronicle*, Aug. 8rd.

THE MAGAZINE

OF

THE SCHOOL OF AGRICULTURE,

COLOMBO.

Added as a Supplement monthly to the "TROPICAL AGRICULTURIST."

The following pages include the contents of the *Magazine of the School of Agriculture* for September:—

HOW DOES SCIENCE HELP AGRICULTURE?

III.

BY C. DRIEBERG, B.A., F.H.A.S.

Next in importance to Chemistry as an aid to Agriculture is Botany. Through Botany we gain a knowledge of the nature and life-history of all our cultivated crop, and forest trees. We learn thereby how plants take in their food, the sources whence they get this food, the condition in which it is assimilated, how the crude materials are brought to the place where the manufacturing goes on, and how they are elaborated into organic substances, by what means these latter are circulated throughout the plant to meet its wants, how they go to build up the tissues of the plant and cause it to grow, how it reproduces its kind, and how the seedling from the parent plant springs up and goes through the cycle of vegetable life; in fact the whole process of nutrition, growth, maturity, and decay is made clear to us. For if a knowledge of the physiology of man is necessary for the proper nutrition of the body, and for preserving it in health, a knowledge of the physiology of the plant is none the less necessary for its proper care, for keeping it vigorous, for helping it when it suffers from innutrition, for meeting its partiality for conditions of heat or cold, sunlight or shade, and for soil of varying character. By elaborate experiments in Germany in water-culture, plants and trees have been fed artificially, and the quantity and quality of plant food has thus been ascertained. Moreover, through Botany we get to know how plants breathe and the manner in which they are affected by different external agencies. Professor Darwin traces in a most interesting manner the marvellous sensitiveness—almost amounting to intelligence—which some of the individuals of the vegetable world display, and which has only to be observed to command wonder.

The influence of vegetation on climate is another important matter, the influence of forest trees on the rainfall of a country being well known. Since the denudation of the forests in France there has been an appreciable decrease in the rainfall, and Egypt has

had its meagre rainfall increased after the planting-up of the country. Proper shelter both to man and animals means less food, and in cold exposed parts the shelter afforded by a wood is a matter of great consideration.

A knowledge of fungi and bacteria is another important tribute of Botany. Parasitic fungi are among the greatest, if not the greatest, enemies of higher vegetable life, and indirectly of animal life by the loss which their mischief results in. Sometimes this latter effect is directly so, as in the case of ergot which causes much loss among cattle farmers in Great Britain. Ergoted grain is now acknowledged to cause those epidemics of abortion among milch cows which periodically visit certain localities. In Hungary where the flour of rye, the favourite host of ergot, is used for bread, there has been a loss of some thousands of souls by the use of ergoted grain. In our own island too there are parasitic fungi which suck the life-blood, as it were, of the trees that yield us produce; and though some crops may stand the trial, there are others that show, to a sad extent, the effects of the attack, as the paddy does by its "smutted" grain.

There are still left the bacteria, which play such havoc among our cattle and domestic animals by spreading anthrax, pleuro, tuberculosis and other deadly diseases (rabies among the number according to M. Pasteur).

In Ceylon we seldom sow grass seed, but where this is done systematically it is necessary to find out that the seed supplied by the seedsman is pure. It was a common practice, till consulting Botanists were appointed to Agricultural Societies, to largely adulterate seeds; sometimes substituting inferior grass seeds for a superior kind, and at other times using some totally artificial adulterant. It is often impossible to detect the fraud till after a botanical examination.

A knowledge of weeds and the best means of eradicating them is important to the cultivator. A weed has been well defined as a plant out of place, and where it occurs it robs the useful plant of the nutriment intended for it, only in a less excusable way than the parasitic fungus, for while the weed steals the crude materials, the parasitic fungus steals the food when it is prepared and ready for use.

The interesting subject of fertilization, and the advantages of a knowledge of the process, have already been dealt with by a writer in this magazine.

The various adaptabilities of flowers for bringing about fertilisation form an interesting study in themselves. Mr. Martin John Sabin, of the well-known firm of seedsmen, writing on plant-improvement says:—"Cross-fertilization and selection have done such wonders in this direction that it is difficult to condense the history, as it would be for Agriculturists of 1839 to believe their own eyes, if they could see the crops resulting from half a century's application to the subject of plant-improvement."

SOME USEFUL TREES.

By H. D. Lewis.

The Bael Tree (*Ægle Marmelos*).

This is a middling-sized tree, armed with sharp spines, commonly met with in the warmer parts of the island. It belongs to the natural order Ruacœæ. Its Sinhalese name is Bell-gaha, and its Tamil name is Vilva maram. The tree is considered to be very auspicious, and it is frequently alluded to in ancient Sanskrit poems as an emblem of increase and fertility. It is held sacred by the Hindus, the leaves of it being used in the worship of Siva. Its flowers are of a greenish white and are very fragrant. The fruit is a large berry composed of a smooth hard shell 2-4 inches in diameter, variable in shape and somewhat like an orange. The interior is divided into many cells containing woolly seeds covered with transparent glutinous matter. In India the tree is found cultivated everywhere in Hindu gardens. The fruit is also exported to Europe, principally from Bombay, to be used medicinally. The commercial article is principally the thin dried slices of the unripe fruit. The pulp of the Bael fruit is recommended as a remedy of much value in diarrhoea and dysentery, in irregularity of the bowels and in habitual constipation. The ripe fruit is considered as cooling and laxative. The pulp of the half-ripe fruit baked and mixed with sugar and rosewater when given on an empty stomach is said to be a good remedy for diarrhoea and dysentery. The bark of the root is given in compound decoctions in intermittent fevers, and the leaves made into poultices in ophthalmia. A decoction of the bark of the stem is given in palpitation of the heart and a decoction of the leaves in asthma. The fresh juice of the leaves is given with honey as a laxative and febrifuge. The root boiled with the seeds of *Panicum Italicum* (S. Tana-hal) is used in native Veterinary medicine in case of cattle murrain.

The extract from the flower, called in English marmel water, and known in Sinhalese as "Pinidiya," is used by the natives as scent on festive occasions. It is also sometimes added in the preparation of sweetmeats for flavouring them. During the flowering season boys and men in the villages surrounding Colombo may be seen plucking the flowers and bringing them in baskets to the town for sale, where they are readily bought for distillation. An infusion of the flower is also used as a cooling drink.

Coccinum Fenestratum.

This is a medicinal creeper of the Merispermaceæ order having a cylindrical woody stem from 1-4 inches in diameter, commonly met with in jungles in the warmer parts of the island. Its Sinhalese name is Weni-wel-geta, Ban-wel-geta or Kaha-wel. It is known in English as Tree Turmeric, False Calumba or Knotted plant. The stem is covered with a pale corky bark, and when cut is of a bright greenish yellow colour. It is of a porous structure having no concentric rings, but conspicuous medullary rays. The leaves are alternate, cordate, entire, 5-7 nerved smooth and shining above, very hoary underneath. In the young plants the leaves are frequently peltate. The flowers are in umbels and are of a greenish colour. The stem forms a bitter tonic which is considered by the natives as an excellent stomachic and a popular

remedy for fever, also as having the properties of promoting appetite and curing bloodshot eyes. It is also considered to be a good medicine for tetanus. It is used at the present time in the hospitals of the Madras Presidency as a bitter tonic.

The plant also yields a strong cordage and a bright canary yellow dye. The dye is obtained by boiling the chopped stems in water, and it is used by the natives for dyeing rushes &c., which they use for manufacturing ornamental baskets &c. The freshly-cut stem of the creeper exudes a large quantity of liquid which the natives often suck for allaying thirst when they cannot find water in the jungle to drink.

(To be continued.)

NOTES ON SOME OF THE GEOLOGICAL FORMATIONS IN CEYLON.

III.

By C. DRIEBERG, B.A., F.H.A.S.

Before passing from the subject of limestone, I propose to notice briefly the modern minor limestone formations.

Calc-cinter.—Water alone has not the power of dissolving calcium carbonate, but water with carbonic acid gas in solution easily dissolves it; and since lime is one of the commonest constituents of rocks, underground water generally contains carbonate of lime in solution to some extent. In regions, however, where limestone rock prevails, the springs and rivers and streams contain carbonate of lime in large proportion. Such waters are then said to be "hard," and are not suitable for domestic purposes owing to the difficulty with which they form a lather with soap. Now if such "hard" water be boiled the carbonic acid gas in it, which is the means of keeping the calcium carbonate in solution, is driven off, and there is a deposition of calcium carbonate. In nature a similar process goes on. When certain springs highly charged with calcium carbonate issue out of a rock, part of the carbonic acid gas is evaporated, and of necessity part of the calcium carbonate in solution is deposited in a solid form. Springs of this kind have got the popular name of petrifying springs, for any substance placed within the reach of them, are, after a time, covered over with a coating of carbonate of lime, giving it the appearance of a stony structure. There is moreover a deposit of this substance continually being laid down at the point of issue of the spring, owing to the evaporation of carbonic acid gas. This is to be observed in Bintenna, where the deposit is collected by the natives, and is prepared for mixing with betel-leaf for chewing purposes.

The formation of *Stalactites* and *Stalagmites* also owe their origin to the property of water with carbonic acid gas having the power of dissolving calcium carbonate and afterwards depositing it on the evaporation of the gas. Under old road bridges small deposits of calcium carbonate may be observed. This is due to the water soaking through the bridge with calcium carbonate in solution and depositing it ere the water drops down below. In limestone regions this goes on to a large extent in underground caverns. The interstitial water percolates through the superincumbent rock till it issues at the top of the cavern; here each drop hangs for a while till it gathers bulk, during which time evaporation goes on and a deposit of a thin pellicle of calcium carbonate results. Eventually the drop of water falls to the bottom of the cavern, and there deposits the rest of the calcium carbonate owing to the loss of the remainder of the carbonic acid gas. The dripping of water continues, and each drop of water leaves its deposit behind. Thus, slowly there descends from the cavern-roof an icicle-looking structure, while from the cavern-floor there ascends a similar process. The former is the stalactite, the latter the stalagmite. By growth these processes often meet, and grow in circumference; and often a beautiful crystalline structure is superinduced, reflecting various colours, while a grotesque

form of carved work is represented. Thus it can be imagined how striking is the effect produced in one of these limestone caverns, where the whole structure seems to rest on beautiful columns of Nature's own architecture, which appear to have been intentionally designed for the purpose of support. Though I am told that stalactitic caverns exist in the island, I can gather no definite information on the point, but the appearance of small stalactites may be observed under old road-bridges or culverts.

Coral Formation.—Coral reefs flank many parts of the coast of Ceylon, and the barrier reef on the S.-W. coast is familiar to most people who have travelled south by the sea-side. Here we have an organically-formed structure, the organic agent being the coral zoophyte, which has the power of appropriating the carbonate of lime in the sea for building calcareous structures for themselves. These reef-builders require a temperature somewhat above 68° F. to flourish, and they do not thrive below 100 feet below sea-level. The extent of the coral-builders' work may be imagined, when it is said that the great barrier reef of East Australia varies in breadth from 10 to 90 miles and extends for a distance of 1,250 miles. A barrier reef is one that rises up in front of a steep shore,—the mainland or an island—between which and the reef is a body of water, while a fringing reef is one that extends from land seaward till the limit of depth at which the reef-builder flourishes is reached. An atoll again is a lagoon surrounded by a ring of coral. The theory of Darwin to account for these formations is as beautiful as it is ingenious. Darwin supposed that an atoll began by being a fringing reef, next a barrier reef, and lastly an atoll. The fringing reefs, he supposed, were formed round some island. His great hypothesis, however, was that there was a gradual subsidence of the sea-bottom which kept pace with the rise of the coral bed, as the result of the coral-builders' work. Thus the barrier reef would naturally follow, and after the subsidence of the entire island below the sea-level, a lagoon would take its place, the result being an atoll.

This explanation, however, is now rejected by geologists as the result of further research in this direction. Mr. Murray of the "Challenger" Expedition, supported by Professor Agassiz, has been instrumental in overturning the long-accepted theory of Darwin. Mr. Murray, in the course of his observations, discovered that the islands round which, or upon which, the coral builders are at work, are of volcanic origin, and show no trace of subsidence. They are exclusively made up of volcanic material, and none which are below the sea-level, as the bases of an atoll, shows any of the unmistakable evidences of having been at one time above sea-level. This at once did away with Darwin's romantic, though, it must be admitted, rather sweeping hypothesis, as to the mutual understanding between the coral builders and the Plutonic agencies of the earth. In contradistinction, Mr. Murray accounts for the lowering of the level of these volcanic islands by the more matter-of-fact and acceptable explanation, that it is owing to the disintegrating action of the waves, which thus brings the island within the sphere of the coral-builders' work; while submarine islands may have had their level gradually raised to the required elevation by accumulations of organic remains. This, agreeing as it does with other well-known geological results, is a very plausible theory. Thus, reefs growing upward from submerged banks would form atolls; while fringing reefs and barrier reefs would form round islands of higher levels. It is known by observation that certain areas on our globe do undergo, and are undergoing, a process of gradual subsidence as described by Darwin, and Mr. Murray grants that certain atolls may owe their existence to such a phenomenon, but an overwhelming amount of evidence militates against any attempt at making Darwin's hypothesis account generally for the formation of fringing-reefs, barrier-reefs, and atolls.

Old coralline formations appear as the coral-rag of the Oolitic period, and the coralline crag of the Pliocene period. There are some splendid specimens of coralline structures in the Colombo Museum

LIFE-HISTORIES OF INSECTS INJURIOUS TO VEGETATION IN CEYLON.

II.

BY ABA.

Insect-eggs.—Insects pass through many changes of form attended by remarkable changes in their habits. These changes or *metamorphoses* as they are technically called might cause the same insect, at different stages of its life to be mistaken for so many different animals. The first stage in which the greater part of insects appear is that of an ovum, some few however are produced alive, as some fly-maggots and the summer broods of the aphides. Insect-eggs vary much in form and color. They are either oblong, round, conical or oval, and are yellow, orange, blue, &c.

Larva, commonly known as maggot, caterpillar and grub, is hatched from the egg, except in the cases before mentioned. The *larvæ* differ materially according to the different tribes to which they belong. There are some insects, however, which undergo no change of shape, as the grasshoppers and crickets. These are hatched from the eggs complete in all their parts, and undergo no further change than that of casting their skin from time to time and gradually increasing in size, till at length they acquire a perfect resemblance to the parent insect. *Maggots* are produced from the eggs of two-winged (*dipterous*) flies, bees or wasps. They are of a white or grey color and legless. The *larvæ* of moths and butterflies are called caterpillars. They are very often beautifully marked and are furnished for the most part with a pair of articulated feet on each of the three segments behind the head, and pairs of fleshy appendages called sucker-feet on some of the other segments, and at the end of the tail (known as the caudal proleg). Grubs are hatched either from the eggs of weevils or beetles. The best known are those of the cockchafer which is so destructive to vegetation. But whether in this shape or in the shape of a maggot or caterpillar or whatever kind of insect it may be at this stage of its life, it is scientifically known as a *larva*, a Latin term which means, a mask because in this stage the future form of the insect is masked or concealed.

In the larval stage the insect feeds voraciously and often grows rapidly. With the growth of the insect the skin does not expand beyond a certain limit, and when this point is reached the larva ceases feeding for a time, during which the skin loosens, cracks and is cast off. This operation is called *moulting* and occurs from time to time till the larva reaches its full growth. At each moulting the larva comes out in a fresh coat, sometimes like the previous one, but very often of a different color or differently marked. The duration of life in the larval stage varies from a week or two, to a period of three or four or even five years, as with the wireworm and dragon fly.

Pupa.—When the larva attains its full growth it ceases to feed and seeks a shelter in which it may change from the state of *larva* to that of *pupa*. For instance, a caterpillar after feeding till it reaches its full growth retires into some place of concealment, casts off its caterpillar-skin and appears in an entirely different form. In this new form the insect seems for the most part to be a lifeless oval, oblong or conical body. In the different tribes of insects the *pupa* or *chrysalis* (the term is used in the case of moths and butterflies) differs as much as the *larva*. In the majority of the beetle tribe it is furnished with limbs which are cased in sheaths and folded beneath the breast and body. The *pupa* of the butterfly on the other hand is quite destitute of limbs and merely exhibits a writhing motion when touched. It is very often adorned with golden spots or otherwise beautifully marked, hence the name of *chrysalis*. The *pupa* of the locusts and grasshoppers differ only from the perfect insect in having the wings incomplete. In the fly tribe the pupa is perfectly oval, without any motion or distinction of parts. The *pupa* of the dragon-fly is very active and lives in water, but differs very widely in appearance from the perfect insect. After resting a while in the pupal state, an inward

struggle begins, presently the pupa-skin bursts open, and from the rear issues the insect, now fully formed. It will grow no more, both its internal as well as external structure being complete, and it is now known as the *imago* or perfect insect. In the perfect state insects usually are of two sexes, male and female, but in some instances as with the white ant, wasps, &c., there are partly developed females known as "neuters" or "workers." This stage usually lasts only a short time—in some instances a few days or even hours is the extent; in others the insects find some shelter to pass the winter and reappear with the return of warmth and sunshine. During this perfect state the insect has only to support life. Pairing soon takes place and the male dies, but the female is very tenacious of life until her eggs are laid.

(To be continued.)

PADDY CULTIVATION AND TRANS-PLANTING.

(Continued.)

By W. A. DE SILVA.

Choice of Seed is as important as choice of variety. Little if any attention is paid to this by paddy cultivators in the island, and this neglect may be set down as one of the causes of the decreasing yield of grain. A great deal of importance is attached to this matter both in Europe and America, and there are special Acts passed in France to regulate a supply of good seed-grain. Only good seed from vigorous plants should be selected, and when this rule is observed, a seed of excellent seed stock will be eventually got. Again, by a selection of seed certain characters could be developed, and often from one ear of paddy a selection of seed may be made to produce different qualities of grain. To prove the important influence of good seed paddy on the yield of the crop, I quote the following account of an experiment with seed grain, by Professor Tanner:—"Two crops were grown on similar land under like circumstances as regards climate &c.; in one case good and suitable seed was used, and in the other case selection and improvement of seed had been neglected. The results were 1 012 lb. of grain from the plants where good seed was used, and only 307½ lb. from inferior seed." In this instance the good seed caused an increase in three times as great as the former yield. But not only do the crops from good seed increase in yield, but they are also less liable to the attacks of injurious insects and fungi, and are better able to withstand extremes of weather. In selecting good seed age must be considered, for both new and very old seed have to be avoided. The former though they come up soon, grow rapidly, and produce very early crop, but do not give a full yield; while the latter either will not come up at all, or produce weak plants. One year old seeds are best fit for the nursery.

A change of seed is often attended with very great benefit. The continual growing of seed grown in the same field or district tends to decrease the yield gradually, and a change of seed from another district of different soil and surroundings produces better results. Some experiments were carried on recently by Mr. William Jansz of Galle and gave most encouraging results. From a report sent by him to the *Tropical Agriculturist* we find that both the crop itself and the produce of rice were increased. For 8 bushels obtained with the old seed, 11 bushels were obtained with imported seed grain, and this in spite of much damage to the crop. This means an increase of 37½ per cent. And in husking the paddy obtained from the imported seed yield 16 seers against 14 yielded by that grown from local seed, an increase of 12½ per cent. These results are very encouraging, and if Mr. Jansz as stated, is following up his experiments, we may hope for further information.

It is important too that the seed should be pure, as a mixture of seeds would mar the success of the crop.

Preparation of the Nursery.—The seed-bed of the nursery should be as carefully prepared as possible.

The land after being thoroughly dug up, should be well exposed to sun and air, and the weeds effectually destroyed in this manner, or in the irrigation, or by both means. After letting on water the land should be again cross-ploughed or puddled or dug and brought into a very fine state. As the space required for a nursery is comparatively small, this should be thoroughly done, and some manure should if possible be added. The great object of all this is to get as vigorous and promising plants as possible. Before sowing, the seed should be steeped in water to assist germination. Different methods of germinating the seed are followed in different districts. The following is an elaborate though useful process. The seed paddy, after being soaked in water for a night, is laid on the floor to form a bed six inches deep, covered over with leaves and mats, and weighted down. After remaining thus for from 3 to 5 days, it is again steeped in water, and this time bedded a foot deep on the floor covered with leaves, but without weights, so as not to injure the sprouting seeds. After two nights the seed is ready for sowing. This is a time-honoured custom among some of the goiyas, the result of practical experience, and attended with advantages they cannot explain the reason of. The pity of it is they do not all adopt it, and that they should be too slow to adopt means whereby their food-supply will be increased. Another peculiarity among the goiyas is that just those who are less favoured in the richness of their land and the supply of their water are the more careless, while those who have the advantages of a good soil and an unailing water supply are the industrious class.

When germinated seed, which has been sown in the prepared nursery is up about 2 or 3 inches in height, water should be turned into it at intervals. (The subject of irrigation, however, I shall deal with more fully on another occasion.)

The nursery can be prepared with success on a piece of high land, if there is any fear of rain interfering with its success in the low ground. In that case the plot after being prepared and sowed with ungerminated seed, should be watered twice daily until the plants are ready for rooting up.

Plants obtained from 8 seers of the ordinary kinds of paddy would be sufficient to transplant into an acre of land, while as much as 2½ bushels would be necessary for broadcasting. In practice it is always advisable to put down at least 12 seers of paddy, and select the best plants only for transplanting.

(To be continued.)

NOTES FROM AGRICULTURAL STATIONS.

KEGALLA, 14th August 1889.

A part of the experimental garden is under cotton, the varieties being Egyptian, American, Sea Island, and Peruvian, in rows three to six feet apart. The young plants are thriving well. Between the rows of cotton I have some India corn growing, and observe with satisfaction that they appear to thrive better than in most of the chena lands. I have also planted some arrowroot and tobacco on a small scale, both of which give good promise. At present I am getting a plot ready for dholl. The weather during July has been generally wet, and particularly so during the latter part of the month.

J. W. P. SAMARASEKERE.

AKMIMANA, 4th August 1889.

These gardens are situated about 6 miles from Galle. Akmimana is a pretty large village, the inhabitants of which depend on paddy cultivation for a living. The paddy fields are fertile, and irrigated by a stream running across the tract.

At present there are plots of arrowroot and dholl. Last month was occupied in clearing and cleaning land for cotton and other crops. This new land, to which I intend shortly removing, will admit of cultivation on a larger scale than has hitherto been carried on by me. The paddy crop is now quite ready for cutting, and will be harvested early in August.

P. SAMARASEKERE.

HAPPY VALLEY, Haputale, 5th August 1889.

My work here is of a different nature from that which I had in my former stations. Your readers might have heard of the grant of land—200 acres in extent—made by the Government to the School of Industry here. Two hundred acres form a large extent, and there is room for agricultural work on a large scale. I consider it an honour that I have to initiate this work and a privilege that I have so worthy a Director in the Rev. S. Langdon. Although there is a good deal to be done, my work is yet in the experimental state. We have yet to find out what crops are best suited to the climate, soil, &c., which will pay best, and the most suitable time to grow them. So far barley, cotton, dholl, and potatoes have engaged our attention. There is moreover a nursery of tea containing seedlings sufficient to plant about six acres. We have also in a nursery a large number of cuttings of different varieties of Australian grape-vines, kindly sent us by Mr. A. M. Ferguson, C.M.G. and Mr. Nock of the Hakgala Gardens. There is a garden where English and native vegetables are grown for school consumption only; but in time it is hoped that the produce will be large enough to admit of an outside sale. A fine bit of coffee land—some $\frac{3}{4}$ of a mile off—was lately purchased for the school and is also under my supervision. There is no assweddumized paddy land attached to the school, but if my work here will admit of it, I am anxious to have a piece of arable land in the adjoining village cultivated with the "Howard's Cingalee plough" for the next season. The weather was dry during July with a few showers at the back end of the month. The showers have done much good to the coffee which has since begun to blossom.

Slowly but steadily the foundation of a regular farm is being laid, and we can already count some sheep, swine, and poultry of superior breed. There are also a number of cattle, and the manure from these is stored according to the 'pit' system.

EDWIN T. HOOLE.

CORRESPONDENCE.

CHENA CULTIVATION.

SIR,—Chena cultivation is a branch of native agriculture which has existed from time immemorial, and which in times of scarcity has served to mitigate the effects of a general famine. That chena cultivation was known and practised in the island long before paddy cultivation was introduced, may be safely assumed. There was one consideration which rendered chena cultivation during the early period of the native monarchy a matter of necessity, as the only means of opening up the country and driving away wild animals from the vicinity of villages. Another advantage may be found in the abundant pasturage which a newly-reaped chena afforded. Besides this advantage it offered also the only field for raising vegetables and yams on which the villagers almost wholly subsisted. But above all, the strongest reason for the encouragement of chena cultivation at that time may be found in its application to the cultivation of cotton. The chena furnished the material for clothing, and until the looms of Manchester commenced to undersell the native cotton spinner, cotton grown on the chenas supplied clothing to our rural population. Much difference of opinion seems to exist, whether chena cultivation as now practised should be altogether prohibited or not; as an argument for the former may be mentioned the unwholesomeness of all dry grains as an article of constant and regular diet, the serious injury done to forests by indiscriminate chena clearing, and the diversion of the industry of the people from the more important occupation of paddy cultivation. I shall notice these objections before dealing with the other side of the question. First then, as regards the unwholesomeness of dry grain as an article of constant diet, we have seen and read of its effects on the population of places where rice forms but a small portion of their food. There is no doubt that the consumption of dry grain is attended

with many and serious evils. These places have become the centres of endemic fever. Immediately after the fine-grain crop is taken in, and that too in the unhealthiest season of the year, fever and dysentery begin to set in. Dysentery is always higher during this season, and with the inability to get more nourishing food, even when suffering from sickness, the poor people if they recover at all owe it to a naturally strong constitution.

The injury that is done to forests by chena cultivation, except in the mountainous and remoter parts of the island, is perhaps too exaggerated. The lands once cleared unless systematically planted with forest trees will not produce for a very long time a single valuable tree. The seeds that are burnt and destroyed are never replaced, and the rapid growth of jungle plants serve effectually to keep down the seed of a forest tree that may have germinated. If chena cultivation is suppressed for the sake of getting the people to take more to paddy cultivation it would be a good policy. I very much doubt these scrubby jungle plants becoming forest trees. It is believed that the native takes to chena cultivation as it is easier than that of cultivating paddy. It is not from choice but from sheer necessity that the native takes to it. The large areas of chena land that are wholly inapplicable for any other kind of cultivation, instead of lying unutilized may be used for the cultivation of grains, legumes, gram, collu and Indian corn. A ready market will be found in our larger towns for these products for the feeding of horses and cattle. It is only in districts where paddy land is not available or where it is dependent on season rains that chena cultivation is resorted to. Though dry grain is unwholesome it must be granted that it has proved the means of saving the people during the times of drought and famine. Again and again we have heard it stated that the unwholesomeness of dry grain is due to the preparation of it.

Yours, &c.,

ALFRED DRIEBERG.

School of Agriculture, Colombo.

GENERAL ITEMS.

Mr. Robert Stevenson of East Lothian, deduces from numerous experiments that every 100 lb. liveweight gives butcher's meat 57.7 per cent; tallow 8 per cent; hide 5.5 per cent; and offal 28.8 per cent.

A course of lectures on Forestry has been established in the Edinburgh University, and will open with the Winter Session this year. The lecturer will be Dr. William Somerville, whose agricultural career in Edinburgh, London and Germany was a phenomenal success.

It was stated at a meeting of the Abroath Analytical Society that the keeping indoors of cows during the day in hot weather and letting them out to graze at night, appreciably increased the amount of butter in milk yielded. This is a valuable hint to owners of cattle in hot climates, if only the necessary protection against cattle-raising was provided us.

A new edition of Prof. Wallace's book on "The Livestock of the Farm" is just out. The work has been enlarged and illustrated. The first edition was brought out in great haste, and wanted revising badly. The new edition, says the *North British Agriculturist*, "is as different from the first as the finished linen is from the unscutched flax. It is thoroughly revised, the information being brought well up to date, and it is embellished by over a hundred illustrations."

Mr. C. G. Johnson of Croft, Yorkshire, a well-known advocate of Ensilage, has published a report of his mode of farming, especially in reference to his use of Ensilage for feeding purposes. Mr. Johnson, in the rearing of his calves, gave each cow two calves to rear for a few months after calving, then only one, and fed the cows only on Ensilage, so as to test its merits for milk-production and calf-rearing. The animals were healthy and in good condition. His young stock were fed on Ensilage alone without cake or corn, and they appear to be getting on exceedingly well. The farm horses are fed on silage alone, with good results.

THE TROPICAL AGRICULTURIST MONTHLY.

COLOMBO, OCTOBER 1ST, 1889.

[No. 4.

TANNIN IN TEA.

WE have heard that disappointment has been expressed in regard to the analyses of Ceylon tea at Melbourne in 1880, (see page 211) because, instead of discriminating tannin, "total extract" was given. The course pursued was in full appreciation of the standard by which buyers value teas. The main object with brokers and purchasers has hitherto been, not to meet our wishes, by favouring the use of Ceylon tea on its own merits, but the obtaining of teas strong enough to bear a large admixture of China. What the Melbourne analyses did was to show that for purity and strength the Ceylon teas stood exceptionally high, while the flavour was delicate. The "total extract" obtained by Mr. Dunn was, of course, mainly tannin, and we know by very trying experience, that no delicacy of flavour, however highly it may be appreciated by consumers, will induce brokers and dealers to give proportionate prices for tea. Tea with a small proportion of tannin is a weak tea, and, as a writer in the *Home and Colonial Mail* very sensibly points out, the great superiority of Indian and Ceylon teas over those of China consists in the larger amount of tannin in the former. That being so, when Indian or Ceylon teas are used alone, the great mistake has often been to put too large a quantity in the pot for infusion, and—worse still—to continue the infusion for too long a period, so that too large a proportion of the tannin is extracted. Of most Indian and Ceylon teas one teaspoonful is equal to two of the vast majority of China kinds. If the teapot is well heated beforehand, if perfectly boiling water is used, and if a "cosy" is put over the teapot, five minutes or at the utmost seven ought to be the maximum period for infusion. If the tea is required to be kept for a longer period before being drunk, it ought to be poured into a second teapot, which has also been well heated and over which the

cosy may be placed until the liquid is poured into "the cups" [not cup] "which cheer but not inebriate." No practice has brought Indian and Ceylon teas more into discredit than that of allowing the infusion to soak for a quarter or even half-an-hour. In that time a strong but delicate tea becomes harsh and nauseous. The time seems approaching when there will be little or no China tea available for dealers to blend with Indian and Ceylon. When that period arrives, teas which on analysis give a small proportion of tannin may be paid for in the London and other markets in proportion to their delicacy, but as yet the teas which realize the highest prices are, as a rule, those which contain a high proportion of tannin, and so are good for mixing purposes.

FRAUDULENT TEA MARKING.

The details of the case in London, lately published at the instance of the Planters' Association afford ample testimony as to the gravity of the revelations made during the examination in bankruptcy proceedings of Mr. Whitewright of Messrs. Whitewright, Brown & Co. Of course the existence of much fraudulent procedure with regard to the sale of tea had long been suspected and in some degree known; but we doubt very much if either that suspicion or that knowledge extended to anything like the facts divulged during the examination of the bankrupt referred to. It is very certain that to no class more than to the tea planters of Ceylon are these facts so pregnant with warning. Before entering further into the discussion of this matter, we may say that what has surprised us even more than the knowledge of the practices now ascertained, has been the light manner in which these appear to have been regarded by the Registrar of the Bankruptcy Court. It has always been presumed that one of the main objects of investigation intrusted to that official was to take cognizance of, and severely punish, any acts of a fraudulent character which might be ascertained by him. One of his functions consists in an endeavor to safeguard commercial transactions by the upholding of a high standard of commercial morality. Now we apprehend that no one can contend that the

practices to which Mr. Whitewright has so candidly confessed can rank within that standard. More grossly fraudulent proceedings can scarcely be conceived, and the fact that they appear to have called forth no reprimand from the Registrar and have imposed no punishment by him upon the perpetrators of them, seems to demand the strictest attention by all those interested in the production of tea and its ultimate distribution, to safeguard their interests in the future. It is our belief that a strong memorial or protest against the action of the Registrar in this case should be addressed to the quarter by which such officials are controlled; and it surprises us to observe that the remarks made by our contemporary of the *Grocer* should not have included some such recommendation. Indeed, the editorial remarks of that paper go little beyond a mere recapitulation of the facts, and deal with these in so light a strain, that the suspicion is almost forced upon the readers of them that this highly respectable paper, as the representative of the interests of the trade which forms its constituency, fears to call things by their proper name lest it should give offence to many members of the trade by which it is supported.

But we who grow the tea, and who are largely dependent for our financial success on the honesty of those who undertake its distribution, can be under no such apprehension, and can have no hesitation in saying that, if the grocery trade generally is content to abstain from active protest against such practices, it is practically condoning a fraud and by so doing associating itself with responsibility for it. No terms can be too strong to apply to the acts of this bankrupt. We can conceive no transactions which should more justly have included Messrs. Whitewright, Brown & Co. within the class of fraudulent bankrupts. Had the members of this firm, in perhaps a despairing effort to keep their heads above water till the advent of better times, gone on trading after having the knowledge of their insolvency, they would have been so classed and would have incurred all the penalties of fraudulent bankruptcy. But, forsooth, because they have only been guilty of practices which cheat specially the unfortunate producer by damaging the reputation of his teas, they are to get off scot-free! It may be said that in this case it is the extremes which have suffered by the action of the middleman. The retail grocer has failed to get what he asked for, the producer has had his position affected by the affixture of his marks to teas of inferior or blended descriptions. At all events the *Grocer* only bestows its editorial pity on the first of these; it has no word of sympathy for the second, for it simply remarks: "Here is a new pit-fall for the unsuspecting retailer!" We need only quote here one statement made by the bankrupt in proof of our assertion that his acts were fraudulent in the highest imaginable degree. He is reported as having admitted that his firm had sold fifty chests of tea representing it to be of a certain mark and arrived by a particular ship, whereas in reality the tea was composed of teas of three different marks and *ex* different ships, although sold as one kind and not as a blend. This was part No. 1 of the system of fraud pursued. But that this should be successful, a further fraud, the forgery of the marks, had to be carried out, and for this purpose we find this firm to have possessed itself of a variety of stencil plates to enable the forgery to be made. We search the editorial comments of the *Grocer* in vain for any thoroughgoing denunciation of these practices such as we might naturally have expected. But we find no indignation expressed, only the statement that "the

moral of the story must not be omitted. However ingenious (!) Mr. Whitewright may have been in his style of business, he has not apparently made a fortune, and it would seem that his style does not pay." We cannot but feel regret that our contemporary should have placed the "moral" of this case on so low a level as this. To us—as we are sure it will to most of our readers—the "moral" should be sought in a far wider and higher reach; for if it is a question simply of failure to pay, we fear much that there will still remain inducement for unscrupulous men to try their luck in similar courses in hope of more successful results!

CEYLON TEA IN NEW ZEALAND.

Mr. J. F. Wingate writes:—

"In connection with all that has been written about good done by the Tea Fund I send you under separate cover a Christ-church paper. You will see *marked* the different advertisements in which Ceylon teas are now mentioned, 'Ceylon teas are the finest and purest in the world' &c., &c. When I went down to New Zealand I looked over every paper and could find no mention of 'Ceylon' amongst the teas—inquired at the shops: but none seemed to keep it, or would not acknowledge to keeping it. After the distribution of the Tea Fund samples I was constantly asked where it could be got *pure*, and as I could not tell them I said 'Bully your grocer.' In due time you see the result in these advertisements: but whether all offered for sale is the *pure* article I cannot say. It is for you and the Colombo merchants to look up the shipments! My friends in New Zealand are to send me up a few packets just as bought out of the shops, and after testing them, I may have some suggestions to lay before the Tea Fund about the Merchandize Marks Act."

The above is very satisfactory; and this mail brings us a letter from Mr. Wm. Watson who says he is writing fully to the Planters' Association about Ceylon tea for the Exhibition. Mr. Watson has evidently thrown himself heartily into the duty imposed on him. He had been getting large quantities of Ceylon tea previously on private account, so that in acting publicly for the Planters' Association, he is in a manner giving up his little monopoly. But he quite recognises the importance of making Ceylon tea known: the more widely the better.

AN AGRICULTURAL EXPERIMENTAL STATION IN JAVA.—The report of the Committee of the Second Chamber upon the proposal of the Minister for the Colonies to extend the Government horticultural garden at Buitenzorg by the establishment of an experimental station in connection with agriculture in Netherlands India, has been issued. Several members were disappointed, as they preferred granting subsidies to private stations, and they considered it very doubtful whether all kinds of produce could be examined efficiently at the Government's garden at Buitenzorg. Moreover, they expressed fears that this proposal, if adopted, would lead to a considerable increase of the expenditure, and that the establishment of a technologic-institution would be the natural consequence. It was further pointed out that although this measure would tend to the benefit of private institutions, the managers of the estates connected with it had not been consulted. On the other hand, it was argued that a Government experimental station was to be preferred to private ones, which might probably be limited in their sphere of action. Some other members who were prepared to approve the proposal advise the granting of subsidies to private institutions as well.—*Amsterdam Oor., L. and C. Express*, Aug. 2nd.

Correspondence.

To the Editor.

COCONUT PLANTING.

SIR,—I see someone writes: "I cannot conceive why more planters in the island don't turn their attention to coconuts," &c. &c. It is very strange that more do not, seeing that coconuts have been cultivated so long and have never seriously disappointed anyone. I suppose it is the race for wealth: they are too slow. Yet a retrospect will show that those who have gone in for coconuts are more prosperous than any who have invested in other products. Besides, who ever heard of an abandoned coconut estate? If I began again, nothing but coconuts should have my attention.

COIR MATTING.

COTTON CULTIVATION: CRITICISM AND COUNTER-CRITICISM.

DEAR SIR,—I delayed replying to Mr. Borron's letter seeing so many others taking up the subject of "Cotton." Now that the storm is over, I only have a few remarks to make to Mr. Borron's insinuations:—

Mr. Borron, in his first letter about cotton, goes much out of his way and brings in some of his uncalled-for remarks: he wishes to make me say, "Cotton will not pay in Ceylon;" if he had read my letter carefully he would have seen that I referred to planters whom it would not pay better (in our present planting districts) to grow cotton in preference to other products named by me, which paid them much better if proper cultivation is done. I herewith send copies of two letters received about cotton from friends: please publish same with this letter. I require no sympathy from Mr. Borron, I am not despondent, I desired to point out of the difficulty attending cotton cultivation in other countries and make known Dr. Duke's and my own experience in cotton planting to enable my fellow planters to be able to judge whether it would pay them best to try cotton cultivation or confine themselves to spending their money on their present products which can be made to give good profit. Planters have not been inclined to follow Mr. Borron's lead in planting new products (to planters) such as; chillies, bringal, annatto, arecanuts, or in purchasing and planting land at the extreme end of Matala East. Let him prove his own ability before throwing stones at others. Mr. Borron has called coffee defunct. I can show him good old coffee as also some new, looking well and giving good crop.

I did not ask Mr. Borron for figures from his ledger: seeing how one-sided he argues, now I would not accept his figures if he gave them. Mr. Blackett has promised you his figures. So far from my wishing to cry down cotton, I hope Mr. Blackett and others will be able to prove that cotton will pay better to planters than our other products. Planted in some parts of Ceylon where rain or insects do not destroy the pods it ought to pay well, natives especially.—Yours truly,
J. HOLLOWAY.

Woodthorpe, 28th June 1889.

(True copy: extract.)

My dear Holloway,—Sea Island cotton. You are right respecting the pods being destroyed by insects. I planted about 6,000 seeds as an experiment last October and have not got a lb. of cotton from them, all destroyed by thousands of red beetles and other pests.

The cotton was planted on different parts of estate and in the best soil. As you know I have very good soil.—Yours truly,
P. D. YOUNG.

Remark by Mr. Holloway: Woodthorpe is about 3 miles from Katugastota.

Kandy, 5th July 1889.

(True copy.)

My dear Holloway,—I am sure you are quite right about cotton: it will, I fear, be a failure, and all I can hope is that men will not lose much by it.

I have just returned from Middlemarch and all the pods on the Peruvian cotton are full of poochies and the cotton worthless I should say.—Yours truly,

VALENTINE DUKE.

FIG CULTIVATION IN COLOMBO IN DAYS OF OLD: THE FIG IN BOMBAY.

Bombay, 23rd July 1889.

SIR,—As one who has spent the greater portion of his life in Colombo, and being one of your oldest readers, I think I can lay claim to a corner in your valuable journal.

I have read "Arborator's" letter in your issue of the 2nd instant, anent the fig tree seed, and being at one with him in the opinion he has expressed, namely that the tree can be propagated better from cuttings than raising plants from seed, I forward an extract from the "Encyclopædia Americana," for the information of such of your numerous readers who take an interest in the subject. The volume that I have named is I own an old one, but I remember reading the same opinion expressed in one of the latest works, but as I have not this book before me now, I cannot quote from it. The fig tree is very largely cultivated in Bombay and still more extensively in the Deccan, and the practice observed in propagating it is by cuttings and not seed, though the mode practised in the rearing of the tree is entirely different from that stated in the extract. I shall try on a future occasion to send you full details of the method here observed in the cultivation of this tree. Fig trees have existed in Ceylon prior to the time mentioned by "Arborator." When I first came to Colombo—and that was in 1839,—I remember having two fine trees of the finest variety in my own place in Baillie Street, Fort, and it used then to be the pride of many respectable Burgher families who could boast of a yard or compound at the back of their houses to have fig trees planted there. The fig tree being indigenous to hot climates does not thrive so well in cold climates and in places where there is constant rain, as the fruit being exposed to moisture becomes mouldy and insected. K. H.

PLUMBAGO AND MICA.

31st July 1889.

SIR,—I am afraid that the idea you say is common among the natives that plumbago or graphite is metamorphosed mica must be put down to that mode of argument which leads natives to attribute the origin of some things (and even of some insects and animals, as pointed out by a writer in the "Magazine of the School of Agriculture") to others with which they are almost invariably found associated. It so happens that graphite is found principally in the metamorphic system, which comprises the gneiss, mica-schist, and clay-slate groups.

First, what is mica? It is a silicate of alumina, with silicates of potash, magnesia and other bases. The two principal varieties of it are muscovite and biotite. The first is a potash mica and occurs as an essential constituent of granite. It is of a pearly lustre, generally white, but also found of a yellow, brown or even green colour. Biotite is a magnesia mica generally black or dark brown in colour, though sometimes found of a dark green shade. It is not so common in granite as muscovite, and is essentially a constituent of igneous rocks.

Next, what is graphite or plumbago? It is almost pure carbon; and, though some varieties are very pure, it is generally found mixed with from one to five per cent of iron, silica and alumina. Though generally given as not inflammable, when strongly heated in air or oxygen it burns, forming carbonic acid gas. Now both in the case of mica-schist and graphite, the inducing cause of metamorphism is the heat derived from intrusions of igneous rock. Varieties of mica schist sometimes occur almost wholly composed of mica, and not unfrequently a hydrous mica is found with a greasy feel. Now this greasy feel is a characteristic of plumbago, (as also of talc) and the occurrence of a mass of mica of a dark color and a greasy feel would be very apt to lead one to look upon it as a transition form of mica passing into graphite. It is more than likely that the silica and alumina in the graphite were derived from the mica schist (very probably through the medium of the highly heated water or steam), but that is all they have in common. In the manufacture of grey cast-iron, graphite crystals are formed by the combination of the charcoal and iron. This much, however, is certain,—that mica is essentially composed of silicates of alumina, potash, and magnesia, and graphite or plumbago of carbon, and nearly pure carbon. It would hardly appear probable therefore that plumbago was a metamorphosed form of mica.—Yours &c.,
C. D.

[Of course not: like coal it is of vegetable origin. That taken for granted, the interesting questions remain:—Is it still in course of formation amongst our primitive rocks? and if so whence does it derive its carbon?—Ed.]

RICE CULTIVATION: MR. ATHERTON STICKS TO HIS TEXT.

Batticaloa, 1st August 1889.

DEAR SIR,—I thank Mr. Elliott for his laboured criticism on my communications to your paper regarding paddy cultivation: he simply corroborates all I have stated, and does not controvert them in the least.

I can hold a plough with his best instructors, and give him lessons on paddy cultivation, which has been my study since the time Mr. Elliott was in his nursery; but I confess that although I have cultivated some of my fields I could never make them pay 76 per cent! Mr. Elliott talks of his three months' experience compared with my fourteen years' residence in the province: let the public judge between us. If we got some of the "hard bargains," why did he tax them so heavily that they cannot be cultivated without serious loss?

He admits that his assessment as Grain Commissioner "on paper" revised the commutation from R60,000 to R90,000, an increase of R30,000 which I hold is 50 per cent. The fact of his estimate not being realized is owing to the large extent of land being since laid waste by excessive commutation, and the inability of the farmer to meet the Government dues, which by the by is usually paid by "paper currency"!

You can imagine the hardship on those who have cultivated their fields against all odds to procure food for themselves and their family, to keep starvation from their door. God help them if the Government will not.

Nothing that has yet been said disproves my argument as to the evils of the excessive commutation, and its destructive influence on cultivation.—I remain, dear sir, yours faithfully,

EDWARD N. ATHERTON.

[And still, Mr. Atherton says nothing about "bad seasons" which have probably as much as anything to do with local grumbling.—Ed.]

CINNAMON ADVANCES.—We fear that in response to the letter of "B." Mr. Jardine from his long experience will say that the "advance," system to the peelers, is not to be got rid of very readily. Restrictions can no doubt be applied and perhaps by degrees these may be so arranged as to point to a good time when the workers might be induced to do without "advances." It is a case of *Festina lente!*

TEA PROSPECTS AND CULTIVATION.—The Ceylon planters are prepared in the most active and enlightened way to respond to the renewed demand which has set in for their teas in London. They are encouraged by this reaction and the general assurance from experts, that theirs is the tea of the future, to do their very best, by careful cultivation and preparation to send on teas that will give satisfaction. There is further encouragement to our planters in the latest news from China, conveyed by our special telegram, to the effect, that the China exports are 21½ million lb. short. A further cause of encouragement is the increasing demand for fine Ceylon teas for Australia and New Zealand, and Persia, and for ordinary teas for the Bombay market, so increasing the importance of the Colombo tea selling market. Very important analyses of Ceylon (as compared with China and Japan) tea recently effected by Mr. Cochran show the superiority of our teas and give further encouragement to planters.—We are all very hopeful that the people of the United States will yet prove good customers for our teas, and the Secretaries of the Ceylon American Company are busy with Mr. Pineo making all needful arrangements previous to the latter starting on his journey for the West to make known, far and wide, the virtues and the superiority every way of Ceylon teas.

A JAVA TEA SYNDICATE.—The Honorary Secretary of the Soekaboemi Agricultural Association sends up in pamphlet form the report of proceedings of a meeting of this Association held on 14th April last, when, amongst other subjects discussed, that of tea came up. We are told that the President (Mr. G. Mundt) in a lengthy speech called the attention of the meeting to the disquieting fall in tea prices, which the latest news of the sales held in London evidenced. He was of opinion that most of the estates in Java had themselves to blame for the low prices that their produce obtains, through aiming more at quantity than at quality. But the quantities of inferior Java tea that were sent to Europe spoil the market for the better producing estates, which thereby saw their existence threatened. It also appeared to him, judging by reports received not only from the Netherlands but from England and Germany, that the buyers were doing all in their power to lower the wholesale prices to the injury of planters, but that nothing was done to increase the consumption of the article by a corresponding lowering of the retail prices, and this had caused the question to arise in his mind, whether the time had not come to interfere and take the sale of the product into their own hands by means of a syndicate to be formed, on the pattern of those syndicates the object of which was to push British India and Ceylon teas and seek new markets therefor. This speech of the President gave rise to a lengthy exchange of views, in which Messrs. Hofstede, Netscher, Hall, Brevet and Maier took part, and it was resolved to consider more fully the form of the proposed Syndicate at the meeting of the 14th July (since postponed to 14th August).

ELECTRIC TRACTION.—One of the most recent stock-broking circulars (says the *E. T. Journal*), in recommending investment in tramway shares as likely to rise, says: "Lastly, but not least, mechanical traction by electricity is now within the region of practical politics, and its effect upon net earnings may be such as will double the dividend paying capacity of all tramway properties." M. de Lindheim, of Vienna, who has been going very fully into the tramway and railway statistics of Europe, has come to the conclusion that electric traction is the best system. Taking 1 as representing the cost of electric traction, he represents horse traction as costing 1.47.

TOBACCO IN DELI.—A correspondent of the *Delhi Courant*, writing from Holland, sends word of a speculative stir made in the latter country by the rise in the price of tobacco, resulting in new companies coming forwards. Two prospectuses saw the light in one week to attract the attention of capitalists. One of them deals with a concession in Assahan requiring £125,000 to work, and another in Langkat, promoted by Mr. Douglas, who has it in the market for one million of guilders. The fact that the Deli-Assahan Company has raised a yearly crop of eleven piculs of tobacco of excellent quality per field speaks volumes. Assahan, as a tobacco country, has in consequence a decided advantage over Lower Langkat, which cannot boast of such wonders. Dutch capitalists favour Assahan, but London ones feel more disposed to try Langkat. Monied business men in that city look to Sumatra as a promising field for investment, from the proven extent of its tobacco growing capabilities.

A CORNER IN QUININE.—The approach of the dead season has been promptly utilised by a convenient correspondent of the *Financial News* for an attempt to "get up" a correspondence on the position of quinine. The correspondent, who calls himself "Common Sense," in his anxiety to put the readers of the *Financial News* in the way of a good thing, trots out all the familiar "bull" arguments about the abnormal cheapness of quinine and the chance for a "moderate capitalist," with, say, £100,000 to invest in the article, to obtain from 300 to 400 per cent on his money in a very short time. It is remarkable that, within the last two years, we think, two similar attempts have been made in the journal in question to put some life into quinine; but on both occasions these have fallen quite flat. If Mr. Henry Marks, editor of the *Financial News*, proprietor of the *Evening News and Post*, London County Councillor, and Conservative candidate for Bethnal Green, can spare some time from his multifarious engagements, he might try a quinine speculation himself.—*Chemist and Druggist*, July 13th.

COFFEE IN UVA.—It is very satisfactory to learn on all sides of a wonderful improvement of late in the appearance and prospects of coffee in the Uva district. Estates both in Haputale and Badulla which some time ago appeared to be permanently afflicted with bug, and consequently with their coffee going quite to the bad, are pronounced to be comparatively clear, with good crops or prospects such as have not been seen for a long time back. We have the assurance of Mr. James Blackett who inspects periodically the fine group of Haputale estates held by the late Mr. R. B. Downall, now the property of Messrs. Antony Gibbs & Sons, that coffee has wonderfully improved, and as the best practical proof of the change, arrangements to plant tea in supersession on some coffee fields, have been suspended. Uva planters generally seem to think that the worst of black bug, as of leaf disease, is past, and there is a good chance of their being able to conserve an appreciable area of good paying coffee—paying at the prices likely to prevail for a long time to come for the fragrant berry in the markets of the world. We trust this expectation may be realized.

COFFEE PLANTING IN ASSAM.—A Ceylon tea planter writes to us as follows:—"From all I can learn of Assam and its tea planters they want an *Observer* badly to stir them up a bit. ——— tells me they have some coffee growing on the 'garden' he has charge of. It bears *splendidly* and shows no sign of leaf disease, and yet they never thought of extending it! With coffee growing and thriving on their rich soil they would make a fortune twice as fast as in tea, and why they do not give it a trial seeing coffee is so high and tea so low a price is one of the, to me, unsolved mysteries. If we could replace tea with coffee in Assam it would be a splendid thing for the planter, and not a bad thing for us!" This is quite new to us about coffee flourishing. The only coffee we ever heard of in Assam was that planted by Mr. Anderson, who, failing to persuade his brother (Mr. T. C. Anderson) and friends in Ceylon to go in for tea some 15 (?) years ago when they could have made their fortune, was over-persuaded by them to try coffee in Assam! The plants grew well for a time; but unfortunately leaf-disease appeared before the first blossoms and raged so fiercely that we understood the clearing was abandoned. Could it be a part of this field of coffee, however, to which our present correspondent's informant refers?

TOBACCO IN CEYLON.—The result of sale of Ceylon Tobacco ex "Telamon" is not satisfactory, but we can only suppose, in the absence of any information to the contrary that the leaf sent home was of native growth and manufacture. Several experiments have been made with the ordinary Jaffna-cured tobacco, but in every case only loss has resulted. In one instance, we have been told, a small parcel purchased locally and shipped to Bremen was purchased for 5 pfennigs a lb.—a little less than 1d.—but the purchaser a few days after taking delivery came to the conclusion that the best thing he could do was to throw it away, and accordingly did so. Whether the tobacco sold by Messrs. Grant, Chalmers & Co was similar stuff we cannot say, but should think it very probable. Experts say that the ordinary tobacco cultivated by the villagers is too coarse, not only in texture but in the rib for use as covering for cigars, and that its value as ordinary tobacco ranges from 2d. to 4d. a lb. in Europe. Planters on this side must distinctly understand that the high prices paid occasionally for tobacco is only realized by leaf suitable for use as cigar wrappers, and that ordinary tobacco will fetch locally 7d. a lb. In the catalogue sent to us no less than 12 varieties of tobacco are offered for sale as follows:—353 bales Japan tobacco, 20 bales China tobacco, 29 bales Ceylon tobacco, 3 bales Sumatra tobacco, 8 bales Java tobacco, 3 bales Borneo tobacco, 9 bales Turkey tobacco, 2 bales Dubek tobacco, 17 bales Carmen tobacco, 1 bale Mexican tobacco; 6 hds. Kentucky tobacco; 2 hds. Virginia. Prices range from 2½d paid for the Ceylon leaf to 2s 8d paid for the Sumatra leaf. The following is a copy of the catalogue showing prices realized for Japan tobacco:—

50 BALES JAPAN TOBACCO.

Ex "Carmarthenshire" at Japan.

	Cwt.	qr.	lb.
M. C. (in dia.) C. A. J. 2 Bales	2	2	0 each 6½d
10 "		do	6d
7 "		do	6½d
1 "		do	6½d

Compare this with the rates paid for the fine quality Sumatra leaf:—

3 BALES SUMATRA LEAF TOBACCO.

	Cwt.	qr.	lb.
ASA 1 Bale	1	1	15 2s 6d
1 "		do	2s 8d
BTR 1 "		do	3 5 2s

Similar prices appear to be realized for the Borneo tobacco, but how long these will be maintained in face of increasing supplies of such leaf we have not sufficient information before us to say.—Local "Times,"

LOW PRICES FOR PRODUCE.

Four or five sales by auction, "without reserve," have recently been made in Mincing Lane which afford an illustration of the manner in which, during the last decade, the value of many important raw products has declined. A fortnight ago we announced the sale of 1,605 bales Cuprea bark at the cinchona auctions for a sum which was insufficient even to cover the usual warehouse rent from the time of the importation of the goods until their sale. On Tuesday a second and still larger parcel of the same kind of bark was offered under similar conditions. Both lots are understood to have been held by the same owners (a banking corporation), to whom they were pawned several years ago, and who in the near future will probably be able to derive, among all the disappointments of the transaction, some slight consolation from the fact that further delay would only have made matters worse. The quantity sold on July 2nd amounted to 182,000 lb., which realised an aggregate of about 1,900 $\frac{1}{2}$ l., while at Tuesday's auctions 237,000 lb. were disposed of, the total realising about 2,250 $\frac{1}{2}$ l. With some slight exception all this bark was imported during the year 1882, when the imports of Cuprea reached by far the highest figure ever known. In that year a syndicate of speculators, supposed to be in the possession of exclusive information respecting the future supply of this bark from Central America, were trying to "corner" the quinine manufacturers, and, the market being generally unsettled, nearly all the arrivals of Cuprea went in stock. In January, 1882, the best brands of the bark still realised from 2s 9d to 3s 3d per lb., but towards the end of the year the price had fallen to about 2s per lb. If in 1882 the owners of the parcels which have been sold this month, after seven years' warehousing, had decided upon the opposite policy to that which they actually did adopt, and met the buyers at the auctions half way, they would almost certainly have been able to dispose of the entire 420,000 lb at an average price of 2s to 2s 3d per lb and have thus realised at least 45,000 $\frac{1}{2}$ l for what they let go for 4,150 $\frac{1}{2}$ l in July, 1889. It is to be hoped, for the sake of the owners, that they have succeeded in making some arrangement with the dock company regarding the payment of rent-charges on the bark, for if they should have to pay the full regulation rent, that item alone will more than swallow up the whole of the proceeds of the sale. From the prices now realised we may assume that the average equivalent of quinine sulphate in the Cuprea in question is at least 2 per cent. a rather low estimate, though this variety of bark, on account of the cupreine which it contains, is more difficult to treat than cinchona. Taking it at that percentage, however, the aggregate equals about 135,000 oz. quinine, which are now worth, at the most, as many shillings, nearly the whole of the supply having been bought by Continental manufacturers. In 1882 German bulk quinine was quoted at 8s. to 9s. per oz., and we thus see that, whereas quinine-makers can now buy certain classes of bark eleven times as cheaply as in 1882, the product which they obtain from the material has been reduced to one eighth of its price then, a circumstance which assists in explaining why even at the present low quotations they do not cease to manufacture. It would be interesting to know exactly how much of this old Cuprea bark there is still in stock in London. The total quantity of South American bark in the warehouses at the beginning of this month is returned at 36,147 packages, of which 483 are cases. Of the residue, probably not less than 26,000 bales are Cuprea bark, imported for the greater part between 1880 and 1883 and held, we should think, in a very few hands. It would not be a matter of surprise, therefore, if these few holders should have decided to liquidate the whole of this supply in batches such as those offered at the last two sales if they should be able to do so without at the same time still further disarranging the market, or bringing about an accumulation of other American and of Eastern barks. Our stock at the end of the year may be worked down to a moderate figure, and there is then a chance that the position of quinine may become rather better, a heavy stock of bark being always a powerful, though illogical, argu-

ment in support of the "bear" view of the quinine situation. We say illogical, because, whether in the shape of alkaloid in the bark or of sulphate in the tin, the over-supply of quinine itself remains in existence, the only difference being that the bark supply is publicly recorded every month to all the world, whereas the available quantity of quinine is kept more or less secret, and is therefore liable to be disregarded as a factor.

Not unlike the sale of the old Cuprea bark is the disposal, also by auction and "without reserve," of large quantities of cassia lignea, still more Rip-van-Winkleized than the American drug; although in this instance the sacrifice to the holders is not by any means so heavy. On July 3rd a parcel of 1,000 boxes, and on July 17th one of 2,190 boxes, both imported from Hongkong in 1878 and 1880, were knocked down to the highest bidder at from 20s 6d to 21s 6d per cwt., the average price being about 20s 9d per cwt., and the aggregate amount realised for the whole lot near 4,000 $\frac{1}{2}$ l. At the time of its importation this cassia lignea would probably have realised 47s per cwt., or over 9,000 $\frac{1}{2}$ l, and if the full usual charge for warehousing should be made for these two parcels that bill—the tariff for cassia lignea being 10d per ton per week—will figure up to something like 4,500 $\frac{1}{2}$ l. But here also the holders may have made terms with the warehouse companies, and decided to make a clean sweep of their stock of such unprofitable drugs. It would be well if owners of other similarly situated goods would adopt a like course. To accumulate stock and hold it *à outrance* may have been successful policy in the ante-Suez Canal days, and even much later, when London was still the one central market for drugs and most kinds of colonial produce, but it is absolute folly now that nearly every manufacturing country of any importance has established direct communication with the Orient and the West. As foreign nations grow commercially so they will have their share of the world's trade, and all we have to do is to adapt ourselves to the altered circumstances in the best possible spirit.

—*Chemist and Druggist.*

A HOT WEATHER TRIP IN SOUTHERN INDIA:

CINCHONA CULTIVATION.

Under the first heading a writer in the *Pioneer* gives a notice of extensive cinchona cultivation on the Pulney Hills, no doubt embracing the estates Baron von Rosenberg referred to. We quote a portion:—

As we mount the air gradually gets cooler, and about dusk we pass the ridge and reach a cluster of grass huts. This is a frontier station of Travancore for now we have left British territory behind. Here we stop for the night, finding quarters in a grass hut on a not uncomfortable bed of dried straw. We have still ten miles before we can reach our destination, Devikulam, and an ascent of about 1,500 feet; so we start early in the morning. Before us is a long valley shut in on both sides by hills, about 3,500 feet above the sea. Those on the right are very high, from 7,000 to 8,000 feet and from splendid bold cliffs. The whole valley looks beautifully green, with here and there a shola, and at the bottom a small river. At first we descend for about 1,000 feet and then we have again a steep rise, up narrow zig-zags and through thick forest, until at last we go through a pass in the high hills on the right and before us is the station of Devikulam. The view here is as pretty a one as can be imagined. It is of a small circular valley, in the middle a low grassy hill, and all round high hills clothed with thick forest half-way up to the tops. A remarkable feature of the view is the park-like appearance of the grass. The boundary of the forest is everywhere sharply defined, and it looks as if the trees had been regularly planted out so as to produce this appearance. At the foot of the grassy hill, on which some cattle are feeding, is a small lake, and on its bank a bungalow. This is Devikulam, and was the pioneer settlement of the hills.

Ten years ago these hills were almost unknown. They were now and then visited by sportsmen, for the sholas were full of elephant, bison and sambur, and on the tops of the hill there were and still are large herds of ibex. The only inhabitants were a few hillmen, a strange aboriginal race by no means like the Podas of the Nilgherries, who live almost entirely by hunting, felling every year some forty or fifty acres of forest, planting there a crop of raggi and then next year moving on to another shola. The ordinary shepherds from the plains never come to these hills, for they hold them in superstitious dread, believing them to be haunted by devils. About twelve years ago some sportsmen who had visited this beautiful solitude resolved to try and turn it into a planting settlement. They obtained a grant from the Travancore Government of about 100 square miles, containing some 35,000 acres of virgin forest, and then set to work to form a company. Some ten years ago the company commenced operations, and began by planting out cinchona, coffee and tea. The various valleys in the concession contained land suited for each of these crops, the elevations being from 3,500 to 6,000 feet. The actual summits of the hills are much higher, and Analmoody, the biggest of all, is the highest point in South India, being some 80 feet above Dodabett on the Nilgherries. A beginning having been made some others soon joined: and now there are about 16 estates containing about 2,500 acres, chiefly of cinchona, there being only about 300 acres of tea and the same of coffee. Some of the cinchona clearings are now nine years of age and are in full bearing: the youngest are from four to five. There are about a dozen planters scattered over this large area, each of them reigning supreme over some lovely valley, one of the charms being that every valley has a distinct beauty of its own.

The bungalow at Devikulam is a perfect museum of trophies. The walls of the verandah are covered as thick as possible with ibex horns, a mighty bison's head frowns over the mantel-piece, a bear's skin forms a screen some six feet high, an elephant's foot is used as a waste paper basket under the writing table, and the walls are a perfect forest of sambur, antelope and ibex heads. Only yesterday we were perspiring in the plains; but here a wood fire burns brightly in the fire-place, and when after a hearty lunch we draw our arm-chairs up to the fire, light our pipes and toast our toes, we feel that it was worth undertaking the long journey to enjoy this comfort at the end.

On other days we visited the plantation, and watched the barking of the trees, &c. The growth of the cinchona trees is everywhere exceedingly fine. They are almost entirely *C. condaminea* and hybrids. The latter are remarkable for their vigorous growth, and the former are also fine specimens, and show great uniformity all through. Cinchona at present is at a discount; the unit is down to one penny and a half-penny, whereas a few years ago it was a shilling and more. With the unit so low as this the bark must contain a very high average of quinine to pay the planter. Being in a place where such documents are available I took the trouble of examining the sale-lists of cinchona, which are periodically sent out by the London brokers, I was at once struck by the great difference between the prices fetched by Ceylon bark and the bark which is grown on these hills. In Ceylon the prices range from one penny half-penny per pound to fourpence or fourpence half-penny. A few estates range as high as sixpence or sevenpence, but the average of the whole is only about twopence halfpenny. Now it costs quite two pence a pound to cut the bark, pay for freight and put it into the London market: so that planters selling at these prices are selling at a loss. The cinchona grown on the Devikulam hills, however, averages as high as sixpence a pound, the original bark fetching fourpence half-penny and the renewed seven pence, eightpence and even ninepence per pound. On some of the best estates they get as much as five thousand pounds of bark per acre, and with this yield and an average of sixpence there is even thought the unit is so low, a good margin

of profit. The result seems inevitable. Ceylon bark now swamps the London market, but it is impossible that the planters can go on selling at a loss. Many of these estates will be abandoned only those being retained where, at a high elevation, high class trees can be grown. If this is so there should be a good future in store for the Devikulam hills. The company—it is styled the North Travancore Agricultural and Land Planting Society, with head-quarters at Madras—have still some 30,000 acres of splendid forest land untouched at elevations ranging from 3,500 to 6,500 feet, which at the present moment can be purchased at less than half the price that similar land can be bought for in Ceylon. The great drawback of the Devikulam hills is the want of communications. The bridle path by which I rode up is very steep, and even with considerable outlay could never be turned into a cart-road. The result is that in spite of their rich soil and splendid climate the hills are shut off from the outside world, visitors are few and the land finds no purchasers. Whilst I was there I attended one of the planters' meetings, at which this question of road was discussed. What they wanted was a road from the low country on the Travancore side so as to put them in communication with the port of Cochin. This road would run through and open out an immense tract of virgin forest suitable for tea, coffee and cinchona. Being an idle man, with still a few weeks of my holiday to spare, I offered to go on an embassy to the Travancore authorities, in order if possible to induce the Government to sanction the road required. This offer was gladly accepted and I was supplied with any amount of statistics and figures wherewith to back up my argument. For me the journey itself, involving a distance of nearly six hundred miles by road, and back by water, offered considerable attractions. I had long wished to see Travancore, the land of charity as it is called in Southern India, and which is spoken of as a "model State." I accordingly started on my expedition with a light heart.

WHY ARE GEMMING AND MINING LICENSES IN SABARAGAMUWA REFUSED?

MINERALOGY V. AGRICULTURE.

[FROM OUR MINING CORRESPONDENT.]

With reference to your remark that the question should be asked in Council as to whether an offer was made for the right to gem on Crown lands in Sabaragamuwa, I am in a position to tell you candidly that Mr. Maurice Unger, who brought credentials, letters of credit &c. to Ratnapura about 12 months ago; also a letter (I am informed) to the Government Agent from the Governor, came for the purpose of making inquiry about gemming lands, but whether he made any definite offer or not I am unable to obtain authentic information. It is however said that he came from the house of Baring Brothers or the Rothschilds, and offered, as I have already mentioned, one million sterling for the right to gem on Crown lands;* but whether the offer was rejected, or discouraging obstacles thrown in the way, I cannot say.

Gemming is discouraged and almost prohibited in this Province for many reasons, the first and most important being the inability to look after the gemmers who obtain licenses. When two or three men secure a license 20 or 30 proceed to the same neighbourhood and commence operations. Who is to check them? No one except the village peace officer, who usually gets his

* If such an offer was made, it must surely have been for very extensive as well as exclusive rights; and only very objectionable conditions indeed could have led the Ceylon Government to reject so tempting an offer.—Ed.

share, which pays him much better than making arrests, and tramping some 20 or 30 miles to the Courts, beside having to provide food for the prisoners, and sundry other expenses, none of which are recouped by Government. Occasionally, however, we hear of wholesale arrests being made in some forests, such as took place at Patgalkanda, near Ratnapura, some time ago, when about 200 men, villagers and lowcountry Sinhalese, were arrested, by having the jungle (about 500 acres) surrounded with a party of men headed by the Ratemahatmaya and some other Government officials; fines were imposed, licenses refused, and a watchman put on this jungle, but has it stopped illicit gemming? Anyone who chooses to pay a surprise visit will find paths or tracts all through the same land and heaps of illam which has been gathered from under borders of rocks, roots of trees and the sides of streams, abandoned on the sound of voices or footsteps; and by chance you may see the figures of some men flying helter-skelter through the jungle leaving washing baskets, and pointed sticks, for digging out the gravel, behind. So our spirits of adventure are driven from place to place. Whenever any enemy of the peace officer thinks his earnings are too much, petitions go to the Government Agent about his blindness to his duty. Some arrests are made and the offenders taken to Court, and fined a few rupees, which they (the accused) or perhaps the headman indirectly pays; so they go cheerfully off for fresh fields and pastures new and perhaps back to their old diggings.

In some Government lands in Sabaragamuwa the illam is so near the surface, and in fact in many instances the very top dressing of the soil itself, that it is hardly to be expected that the gambling and apathetic native spirit can resist the temptation to turn it over and wash it out, damaging or ignoring the rights of Government, who are not in a position to check or stop it. Consequently all or nearly all licenses to gem on Crown land and large rivers are refused.

A man named Peris and some others leased a piece of about 2 acres of the land referred to above for one year for R600, out of which it is said they netted R30,000, but no renewal of licenses is to be given for the same place [this year, for similar reasons given to those described above. The fact is the natives cannot be honest, and the Government have not provided the means of and don't care to be bothered looking after them, so a fair source of revenue is neglected.

There are many smaller rivers than the Kaluganga in Sabaragamuwa where gemming has been very successfully carried on for years past by natives, such as the Weganga, flowing past Madampe, draining a large extent of country towards the north-east of the Rakwana range flowing into the Kaluganga at Ratnapura, I am not sure if it does not rise in Handapanela jungle, and flow through Everton and Rangweltenne, Messrs. Symons' and Shand's properties, which are well-known to be exceptionally rich in precious stones.

There again is the Hangumaganga which rises in the rich Etoya forest, also Crown property, where illicit gemming went on when licenses were granted, till all permits had to be refused. The above river is also a pretty large one, and flows into the Kaluganga near Ratnapura. The Walaweganga which drains the Balangoda range and flows into the sea on the east coast has been discovered to have in its bed, in places, some of the richest illam ever unearthed, but no licenses are granted in either it or the Kaluganga (the other smaller rivers are at present being gemmed, and have been for centuries past), but I learn on good authority that every encouragement would be given to a com-

pany to gem those large rivers, and the Government Agent would gladly foster and forward the endeavours of any company that may be floated, which would greatly benefit the Province, and in fact, the whole Colony: when the good results of one company is made known, others would doubtless follow. It is only a start that is wanted to prove the richness of our gem-yielding strata. I do not wish to despise our agricultural enterprise by pronouncing it a less paying industry than mining, but surely some of the retired estate proprietors at home might turn their attention to, and become the promoters of, the new enterprise which our colony affords, by getting up a gem and plumbago mining company, which I feel confident would pay the European as well as the native of Ceylon, if conducted on a proper basis.

I hear that our well-known millionaire, Mr. C. H. De Soysa, is likely to purchase some rich gemming land adjoining his tea properties for gemming and planting purposes, and is prepared to give a high price for it. The land is Government forest, about six miles along the Colombo road from Ratnapura, and is called Halpandeniya, containing about six square miles which has been cut into small blocks, and will soon be put up for sale by auction. When the surveyors were at work on this land their coolies who cut the boundaries picked up lots of precious stones. No licenses are granted for gemming there either, but parties were to be met with camped all over the place, who cleared off, leaving their tools and illam behind. I only mention this land as a fine chance for a company to commence operations on. By the bye, one of the adjoining estates' kanganyies used to spend a good deal of his time in Halpandeniya jungle, and it eked out that he had found some valuable gems, where he laboured daily for a couple of hours, so he was told to produce them, the Government Superintendent declaring that he had been gemming on estate land. No gems were forthcoming, but to make certain the Superintendent proceeded into the jungle, and to make a long story short found a ravine honeycombed by the old chap, who upon hearing that his bed of treasures had been discovered, absconded, leaving a wife and family to bemoan his loss, without a share of the valuable stones he is said to have taken with him. Near Kuruwita some rich gemming land has also been surveyed, named Karaparika, 250 acres cut into 9 lots for native gemmers, who pay as much as from R300 to R2,000 or R3,000 per acre, for good land at a Government auction.

Ratnapura is the Sabaragamuwa gem market, the centre to which all the precious stones find their way from the surrounding country, and it presents a pretty lively scene during the busy hours of the day, usually from 8 a.m. till almost dark. You can see men of all nationalities from Kalutara, Galle, Panadure, and Colombo making their purchases at the different gem dealer's tables, and many an hour is wasted over the purchase of a few thousand rupees' worth of gems, beating the owner down to the very lowest, before they close, which probably won't come to pass after all, so off the tamby will march to the next establishment, for he is not in a hurry, thus wasting days over a small purchase, for they cannot close a bargain in a hurry, especially with gems. Any European could buy R10,000 worth of gems in a couple of days of inferior or medium quality, which would take the Ceylon Jew or Moorman a month to battle about. The street in question is about a quarter of a mile long, with houses on each side, which with two or three exceptions are occupied by dealers in precious stones, cutters and polishers, called

lapidaries, who also deal, buy from the villagers, cut and sell to dealers, as well as work for anyone by the piece in the usual way; the value of the stone decides the price demanded for cutting and polishing, from 75c up to several rupees according to the polish to be put on &c. I wonder who is not a judge of precious stone at or near Ratnapura? I must say I have never met him, neither have I found two men who could value a gem the same. They all differ in the valuation, some as much as R30 to R40 on a stone worth about R100, so that no man can rely upon the valuation pronounced by anyone, and everyone must be careful if advised by the seller to go to Mr. So-and-so, for he is sure to have made an arrangement with him. So that one has to pay for their learning, sometimes pretty handsomely too. Those who are supposed to be in respectable positions cannot be trusted any more than the tamby dealer, resthousekeeper, or anyone else. Nothing but careful handling and examining of the gem will disclose its real value, and none but those who have had experience, and have been bitten a few times, can value—any gem especially in the rough—I have even known the practical dealer done most terribly, as the following instance will show. A man well-known in Ratnapura bought a sapphire for R3,000 which he reckoned would fetch when cut into three pieces R10,000, as it was flawed through its whole length 3 inches by about 2 inches; he anticipated being able to secure three beautiful pieces from the sides throwing away the centre. Well, when cut right through the middle trying to secure four instead of three good gems he discovered that the flaws extended to within the 16th part of an inch of the surface all round, and he cut and cut at the gem, till he sold it in disgust for R50, after trying every device imaginable to dispose of it at a fair price approaching what it cost him. Had he immersed the gem in water he might have discovered that the flaws extended to near the surface. Such are the fortunes of gem dealers.

CULTIVATION IN THE MATARA DISTRICT.

COCONUTS, CINNAMON, TEA, CITRONELLA, TEAK AND OTHER CULTIVATION.—THE KEKANADURE TANK.

Under the guidance of the exceptionally intelligent Mohotti Mudaliyar Gunaratna, I had a drive towards Kekanadure, to visit the Government teak garden started by Mr. Elliott, to have a look at one of the many tanks connected with his name, and to inspect the Mudaliyar's own plantation of 265 acres under coconuts, cinnamon, tea, &c. It is evident that no Assistant Agent ever did so much for Matara district as did Mr. Elliott. He had the advantage of a good long continuous spell of residence—1867-1874—and the district in many respects was quite a different place before his coming and after his departure. This is especially true in respect of roads—with which the district is now wonderfully well covered—and irrigation. When the railway comes there will be no want of feeding roads to bring the produce of the interior to the wayside stations and terminus.

Striking into the interior, through one continuous scene of cultivation in one form or other—though with ample scope for improvement—the Mudaliyar pointed out at one turn, the site of the old estate of the Hon. G. Talbot when Assistant Agent at Matara. This was the limit of the road in his day. A rather steep incline here is noted as the scene of the death of a former Secretary of the Matara District Court: he having jumped out when his horse ran away, was picked up dead, and the people ever since call the hill 'Sekaratarikanda.' I am struck with the fertile

soil on all sides: anything can be grown on such land with care, and the people should be well off, but there is the usual indifference about making the most of their advantages and at times, there is far too much absolute idleness and improvidence. For instance, the Mudaliyar tells me that notwithstanding the crowded population on all sides, he has great difficulty in getting a sufficiency of labour to cultivate his estate; in the jak fruit season, many of the people will do absolutely nothing so long as the jaks last! On the other hand in the farther interior it is possible that working for headmen is not fairly remunerated. At any rate the poverty in some parts is excessive, Mr. Rigby of the Wesleyan Mission telling me that in some of their vernacular schools up towards the Morawak korale, he has found children who had not eaten rice for a week or more at a time, living chiefly on roots. The improvidence and indolence of long-engrained habit come in here though, very clearly; for a very small amount of labour on the garden would ensure wholesome vegetables and 'roots' and fruits, as compared with the wild products now sought after when scarcity of food is experienced. A large surplus of the rice grown in Matara district is sold in the coast bazaars where it fetches a higher price than the imported Indian rice—both paying the same tax nominally of 10 per cent. If, in connection with every Government and Grant-in-aid school, there could be a model villagers' garden, cultivated with the ordinary district vegetables and fruit trees by the scholars themselves under their teacher's direction, we might look for improvement gradually, were it only from the habit taught the boys themselves of keeping the ground clear of jungle and weeds. If every rural land-owner in the Matara district, only devoted an hour each morning to cutting down and rooting out noxious vegetation and so giving free play to his fruit trees and vegetables, how great would be the difference in the yield of food products.

The magnificent teak-trees growing in and around Matara, planted 30, 40 and 50 years ago, show that the district is well suited to this tree. The plantation not far from Kekanadure does not however strike one as very flourishing, though some of the trees are of considerable growth. I thought them rather closely planted, but the Mudaliyar assured me that an arboreal authority ruled they were, if anything, too widely apart. They certainly formed a perfect shade even at their present age, but perhaps lopping is all that is required. In 1879, Mr. Fisher when Assistant Agent,—a very worthy successor to Mr. Elliott,—took much interest in teak planting especially about the Hali-ela tank and he made some large proposals about planting 500 acres along the Matara river where the tree was gradually spreading of itself, but it is not likely that Sir James Longden would care to be troubled with a novel and bold proposition of this kind.

A fine young plantation of coconuts belonging to the Messrs. Schokman is first noted before arriving at Mudaliyar Gunaratna's valuable property. The latter has 200 acres under coconuts just beginning to come into bearing at 10 years old, so that although the soil is very good, the climate is not a very forcing one for coconuts, at least as compared with the Madampe and Chilaw districts. Of cinnamon the Mudaliyar has a young clearing, only cut once or twice, of 40 acres. Last year he rented the crop-cutting for R400 and this season he has refused R650. Not much perhaps at R10 to R15 per acre; but a very fair return considering the present price of the bark. The tea field is a young clearing of 12 acres only planted in May last year from Morawak Korale seed. The plants are getting on exceedingly well though, and

this first beginning of tea by a native gentleman in that part of the country, will be pretty certain to lead on to further cultivation more especially with reference to the local consumption of tea among the people who can no longer get coffee.

Climbing to the top of a hill on this estate, I had a delightful peep at Kekanadure tank between two or three miles distant. Framed in by the wide expanses of unbroken forest covering its watershed, the glistening waters of Kekanadure from my vantage point, presented an enchanting picture, none the less attractive for the recollection that its waters were even more useful than ornamental. Unfortunately these waters run dry sometimes when most required, the watershed not being sufficiently favoured with feeding streams to keep up the water supply in dry weather.

Driving back to Matara, by a different route I passed alongside some of the long and wide expanses of paddy-fields fed by the tank, and saw a little of the cultivation for which Matara district is most famous. The continuous wet weather of late had seriously imperilled paddy prospects in some of the divisions of Matara. It was satisfactory to learn that the break now experienced had just come in time, and that the change to "fine" would mean a great deal to the good of the cultivators.

The cultivation of citronella grass in Matara district some years ago rapidly ran up from 2,000 to 8,000 acres; but it is now generally neglected, the prices being so low for the oil and adulteration with water and kerosene having done much mischief. It seems that the test usually applied for adulteration is useless if a little coconut oil be mixed with the citronella, and it is said that the natives who first found this out, made a heap of money!

Several patches of cotton I saw in the district looked promising, and at the Show, as already mentioned, there were a number of samples from different parts of the district. In connection with cultivation generally in the district, I cannot avoid giving the following extract from Mr. Elliott's Administration Report for 1867—the earliest he penned on the Matara district:—

The Dutch had extensive plantations of Areca-nuts and Cinnamon in this District, and a list of the gardens planted with the former fills quite a large folio, which I recently discovered amongst the old records of the Department. I am not aware when these lands were disposed of; most probably, before the arrival of the English, as the monopoly was relinquished in 1790; but the Matara Cinnamon gardens were not sold till 1833 and 1834. Surveys of these, and duplicate title deeds for other lands previously sold, exist in the Kachechi; but during the wild speculation in land which marked the few years before and after 1840, only one European appears to have invested his money in Crown land in the Matara District, viz., Mr. Craig, who purchased 1,472 acres at 6s per acre in 1842. There are other applications on record, but I cannot trace if any sales followed. Of course I do not by this imply that this district was not the scene of any further European enterprise; on the contrary, Mr. Talbot purchased and cultivated one or two extensive Cinnamon gardens, which have since passed into Native hands, and are now planted with Coconuts and Citronella, besides a Coffee estate which he opened and still holds in Morawak Korale.

In another instance, the flat lands lying on the eastern bank of the Polwatte river, were chosen to form a Sugar estate, and purchased from the Native holders at an exorbitant rate; but success did not attend the speculation, and the proprietors appear soon to have abandoned the project, re-selling the ground to the original owners at a considerable loss. They seem however to have gone to work cautiously, as no ruins of buildings on a large scale, or *disjecta membra* of now worthless machinery, remain, as at other places, to mark the scene, to attest the folly or to perpetuate the

remembrance of the injudicious extravagance, which characterized the speculations of the period. No such consolation however exists as regards Paraduwa, chosen by Lord Elphinstone as the site of another sugar estate. Here an extensive Factory and valuable Machinery, with the latest and most expensive improvements, including three or four Steam Engines, were erected, sums varying from 50 to 100,000 pounds are said to have been spent, but fortune, though courted with unbounded liberality, hung back, and the long-sought-for success never came. The estate then fell into Native hands, but was rented by some enthusiasts from Australia, who made extensive plantations of plantain trees for the sake of the fibre, but with no better result. Citronella was then tried on a smaller scale, but was not persevered in. During the past year the whole estate and machinery were purchased at Fiscal's sale for £2,000, by a Chetty; who has most wisely for himself sold off everything movable, to the very tiles on the buildings, for whatever they would fetch, the fittings being, to facilitate matters, unscrewed, and sold separately to suit enterprising Moor dealers in Brass and Copper, while the machinery thus rendered still less valuable, scarcely brought the price of old Iron. The melancholy reminiscence this sight induced was confined to the few English who attended the sale, the vendor or buyers on the other hand seeming rather to enjoy the ruin they were completing, "proud in their office to destroy."

Mr. Baumgartner has given special attention to agricultural matters since he took charge of Matara in August 1886 and his several Reports contain much useful information bearing on the extending cultivation he has witnessed and encouraged in grain, fruit, vegetables, citronella and tea.

PLANTING IN PERAK: DEATH OF AN EX-CEYLON RESIDENT.

(FROM AN OLD CEYLON PLANTER.)

I wish when next you wander that you would come and see this rich and lovely country, the future busy scene of coffee planting, which undoubtedly is to be a success here, and I hope the day is not far distant when we shall have a number of Ceylon men here busily employed in caring for the "Old King" and reminding one of the good old days when he was really monarch in Ceylon. It is only a matter of time, however, I feel sure.

Another Ceylon man has passed away—poor Henry Liddell. He was doing well here, when he was suddenly taken ill (when actively employed at Selama) and taken to Penang, where he died on the evening of the 17th ult. I shall be obliged if you will put an obituary notice of his death in your paper, that his people at home and friends in Ceylon may have an opportunity of knowing of his death. With best wishes and trusting that you and all your Ceylon folks are well. John Cock is hale and hearty and Charlie Wight is flourishing. All we want are a few Ceylon planters with a little "siller" to join us, and while making their own fortunes make Perak better known.

TREE STRUCK BY LIGHTNING.—A correspondent of *Nature* says, that "During the recent thunderstorms a large Elm tree was struck by lightning in a private park at Dulwich, but the only visible effects were linear interrupted grooves about three-quarters of an inch deep, extending down one side of the tree to the ground, where two or three depressions, some 3 inches deep were found. The bark is scooped out as clearly as if done with a gouge, and the intervals are from 1 to 2 feet in length, while the grooves themselves are from 1 to 3 feet in length. The grooves are now filled with mildew, which, I take it, indicates the death of the adjacent bark.—*Gardeners' Chronicle*."

ALL ABOUT DYE STUFFS, OILS, TANNING SUBSTANCES, FIBRES, STARCHES, CAOUTCHOUC, TOBACCO, DRUGS, &c.
FOUND IN CEYLON.

(By the late Henry Meade, written some 40 years ago.)

YE SUFFS.

The coloring substances are very numerous, although many of them are scarcely worth the attention of the merchant, owing to local difficulties in the way of procuring them at a reasonable cost. The art of dyeing, was no doubt, once extensively practised by the Singhalese, but at present it is confined to the fixing of a yellow color on the robes of the priests and to the staining of mats. The dyers have not that command of tints, or that skill in blending them, which is possessed by the Hindus, and the result is, with very few exceptions, that the colored cloths worn by the people are imported from India. There is a small export of Chaya root to the Coast, but it decreases yearly in point both of extent and value.

At the head of the list of Dye Stuffs stands the *Rocella Tinctoria* and *Rocella Fuciformis*, the Orchella weed of commerce. This article was first exported by myself, in the beginning of 1859; it was found growing in great abundance at Calpentyn, and over a range of about fifty miles of the narrow strip of sand, which lies between the Calpentyn lake and the sea. Enormous filaments of the *Tinctoria*, some of them as much as eighteen inches in length, by three quarters of an inch in breadth, were found hanging in clusters on the decayed branches of the oldest mango trees, whilst the mimosas and several varieties of *asclepiadeæ* furnished varieties of the *Fuciformis*, still more valuable. The Palmyra trees and Coconut trees were found to be thickly clothed with the lichen, except in those instances where they had been frequently climbed. There was scarcely a tree or bush that was not covered, more or less, with the *Rocella*, of the worth of which the people were wholly ignorant. It has now become a regular article of commerce.

Except on the tract of seaboard, stretching from Chilaw to Tangalle, the whole line of coast exhibits *Rocellas*, growing more or less luxuriantly, but always confined to a narrow belt of vegetation within the influence of the sea air. On the salt marshes of the western coast, and on the borders of the lagoons it is invariably found, and there is a large growth on the eastern side of the Peninsula at Trincomalee, and about the leways of Hambantota. Where the roots are not torn off, it is reproduced yearly.

Though every variety of *Rocella* is well worth gathering, there are some kinds that are much more valuable than others; and the following simple test will enable anyone to ascertain the comparative richness of the coloring matter which they contain. Fill a bottle half-full of water, put as much of the lichen in, as will leave room to shake the contents of the bottle thoroughly, and add as much

spirits of ammonia as will make the liquor unpleasantly pungent. Shake the bottle occasionally during six or seven days, opening it now and then to admit the air, and at the end of that time the water will exhibit a rich purple color, deepening in intensity for about a fortnight when the maceration is completed. A comparison of the result of different experiments will show the colorific value of the various kinds of weed, and the test is one that never fails. If a lichen fails to impart color to a mixture of ammonia and water it is not a dye stuff, whatever else it may be good for.

The Orchella dye requires no mordant. To fix the color on cloth it is merely necessary to pour the solution above described into boiling water, and immerse the wool or cotton to be dyed in it for half an hour. The dye is not a permanent one, but its extreme beauty will always make it acceptable to manufacturers, who use it to impart a finish to their goods. The value of the weed in the home market varies from £45 to £60 per ton. The latter price was obtained in July last for a shipment of the Ceylon article.*

Casalpinia Sappan.—This very useful dyewood is to be obtained in considerable quantity over the southern parts of the island, and was at one time largely exported. In 1842 nearly 400 tons were shipped to the home market, but since then new fields of supply have been opened, and the trade in Ceylon Sapan is absolutely annihilated. It is procured more cheaply, and of equal if not superior quality, from Siam, Manilla and Japan. The local price here is £6 per ton, a rate which leaves a loss to the exporter. The coloring matter of Sapan is a rather weak red, but by adding lime to the solution or a quantity of Cassia leaves it is considerably strengthened. In a few years' time when the cessation of demand has allowed the growth of trees to be largely increased, it is probable that the Ceylon trade in Sapan may revive and assume its old proportions.†

Artocarpus Integrifolia.—The wood of the Jack, and especially the roots, furnish a lasting and good yellow dye which is materially improved by adding to the bath a limited quantity of the leaves of the Bombee. But though the article would always command a sale in the home market, it cannot be made to any extent an item of profitable export. The wood fetches a higher price for furniture uses than the merchant could afford to give for it, so that it is only the roots and the sawdust that can be considered of value for dyeing. During the last few years it has been cut down so abundantly, that it will soon be necessary to search for the tree in more remote localities.

Vitex Trifoliata.—The Kaha or yellow Mililla yields a very delicate pure dye which the priests use chiefly for giving the required religious hue to their robes. It has been sent home and sold as Fustic, with which it seems to be identical in point of coloring matter. It is not used for furniture like Jack, but is much employed in buildings, and would be barely worth exporting as a dye stuff.

Oidenlandia Umbellata.—*Saya Vaya*.—This variety of Indian Madder grows wild on the western coast, especially in the Akerapattu, where it is gathered, dried and exported to India. It gives out a dull but lasting red color, which local dyers know how to improve by the addition of about five per cent.

* This was written about 40 years ago: the price of orchella weed is now from 20s to 30s, a cwt. The Export in 1888 from Ceylon was nearly 490 cwt.—Ed.

† The price of sapanwood is now £5 @ £8 per ton. The export in 1888 from Ceylon was 3,803 cwt. valued at £20,190.—Ed.

of Cassa leaves. The price realized on the spot is 30s. per cwt., a rate far beyond its worth in the home market, so that the article never finds its way to England. Surprise has often been expressed that it has not been sent home in quantity, but the fact last mentioned furnishes the required explanation.

Lawsonia Inermis.—This sweet-smelling tree, the Maritonda of the Tamils and the Henna of the Arabs,* grows plentifully in the western and northern parts of the island. Its leaves are extensively used by the Muhamadan women to dye their nails red and their husbands are accustomed to employ it in staining the tails and manes of their horses. It might be made an article of considerable export.

Mimocylon Tinctorium.—The Gorakaha of the Singhalese and Cassa of the Tamils is to be found over the whole face of the country, and is a perfect substitute for Sumach, to which it is in reality superior both as a dyeing and tanning material. The leaves should be gathered and dried, in the nuts when they will turn yellow and emit the exact odour of Sumach. The annual import into England is about 14,000 tons, with an aggregate value of £150,000, so the article is one of very considerable importance. The young twigs may be gathered and ground up with the leaves for shipment.

Bixa Orellana.—The shrub which yields this useful dye is a favorite with Bhudist priests, and is usually found growing near their pansalas. The coloring matter† is contained in the casing of the seeds, and can be obtained in the simplest manner. It is only necessary to wash them until no more color can be obtained, and then carefully boil down the liquor to an extract. The seeds give out a very large proportion of color, and as the cake is worth over a shilling per lb., it would pay very well to prepare it. It is used to impart a rich orange tint to silk, and for giving a golden color to butter. It is sent from Brazil and Cayenne in the shape of square cakes weighing two or three lb. each wrapped in plantain leaves or in rolls, not exceeding two or three ounces. Exporters of such articles from new countries would do well to imitate as much as possible the prevailing style of packing and shipping, or their first venture is likely to be disregarded in the home market.

The above are the principal Dye Stuffs in the island, but a thorough examination of its resources in this respect might bring many new articles to light. The leaves of the *Teak* tree make a tolerable red, and yellows of more or less intensity are furnished by several kinds of bark, and the wood of the *Acacia Catechu*, the fruit of the *Embryopteris Glutinifera* and the barks of the *Mangrove* and *Terminalia Alata* make excellent browns. An easy method of detecting the presence of coloring matter in any vegetable substance may be practised as follows:—Take a piece of wool, either cloth or yarn, with two per cent of its weight of alum, and an equal quantity of bichromate of potash. Boil the wool for twenty minutes, then take it out, wash it in clean water, and hang it up in the shade to dry. It is now mordanted or ready to receive the dye, and it is only necessary to immerse it in boiling water again, with three or four times its weight of chips, bark or leaves, as the case may be, and in the course of half-an-hour the coloring matter, if it exist at all, will have been taken up by the cloth. There are some dyes which have a stronger affinity for Cotton, but the cases are rare in which they are not to be exhibited on wool. In such instances the cloth to be dyed must be worked about for half-an-hour in a decoction of Sumach or other astringent substance, and then re-

peatedly immersed in a cold infusion of the supposed dye, care being taken to dry it after each immersion. In this manner, at scarcely any expense and at small cost of labour, the existence of coloring matters may be easily ascertained. That point being settled, the rest is for the consideration of the merchant and the manufacturer.

OILS.

The climate and soil of Ceylon seems peculiarly favorable for the growth of oil seeds. It produces a great quantity of indigenous fatty substances, as well as a number of volatile oils. It is needless to say much upon the wellknown subject of coconut, the oil procured from which ranks first in the scale of importance. An acre of land under native cultivation will yield from forty to fifty nuts a tree annually, but in estates planted by Europeans, the average is not above ten to a tree.* The weight of the nut varies very much. In some cases but little more than 1,000 make up the candy of 560 lb., whilst again there are plantations where 1,500 are required. If 1,250 are assumed to be the average, then the European cultivator gets a candy from an acre and a half, whilst the native realises a ton from the same breadth of soil. The price of "copperah," as the kernel of the nut is termed, may be set down at 70s a candy or £2 7s per acre in the one case and over £9 in the other.† Seven and a half candies of copperah go to the production of a ton weight of oil, worth in the local market say £30 in the average.

The manufacture of coconut-oil is a very simple affair. The nuts are plucked every second month in the dry season, and after being kept in a heap for a few days, the outer husk is taken off, the shell broken, and the kernel put out in the sun. Rain discolours it, but when carefully dried it will keep for months without injury. To convert it into oil by the native method, the copperah is cut into small pieces and put into the checko, which is a part of the trunk of a tree, sunk in the ground to the depth of some feet, and hollowed out for about 18 inches at the top. A beam twenty feet long is fitted into a groove at the bottom of the checko by a sort of a collar, and the pestle, a heavy piece of wood, is secured to the beam by a shifting contrivance. The machine is merely a druggist's mortar and pestle on a large scale, but rude as it is, it is so efficacious, that only a hydraulic machinery of the very best kind can extract more from the copperah. Nor is it really worth while to exert more pressure, as the oil cake is worth 25 per cent of the value of copperah, and if it is too dry it is proportionately less nutritious for the cattle. A full-sized checko will hold 56lb. of copperah, and it takes about two hours to exhaust a charge. The oil is sent to market very dull in color, and contains much more impurities than the article turned out by English machinery, but it commands almost if not quite as good a price and is produced at a cost which beats all competition. To beat the largest and best appointed machinery that can be established, it is merely necessary to multiply the number of checkos, and whether in the outlay in plant, or the expenses in working the native has it hollow. In the one case, deterioration alone costs ten per cent

* A strangely erroneous statement. The yield in the case of European plantations, unless in exceptionally unfavourable conditions, is by far the higher, and is only limited by the amount of culture and manuring bestowed on the trees.—ED.

† Could such a contrast ever have been true?—ED.

* Popularly known as the "country mignonette," from the odour of the flowers.—ED.

† The "arnotto" of commerce.—ED.

per annum, and whether it is profitable or not, all hands from engineer to stoker must be kept on pay as usual, whereas the native manufacturer under like as circumstances, literally loses nothing except the interest on the price of his cheque. The bullocks and their driver are set to other tasks and all are ready to begin at oil-making again when the rates are once more favorable. The export of oil for the past year was 5,709 tons, and will increase yearly, since every day witnesses the planting out of new coconut gardens. There need be no fear of overproduction, for were the supply doubled it would find a ready market. The coconut is a mine of wealth to the inhabitants of Ceylon, and in time will no doubt be made to contribute to the resources of the state, as well as the prosperity of the people.*

Sesame Orientale.—Teel or Gingelly Oil.—This very useful oil, which is in great repute on the Continent, where it is used as a substitute for Olive oil, is cultivated to a considerable extent in the Anuradhapura district, and could be grown almost anywhere as a dry crop. There are three varieties—the black, white, and brown—the white being the most esteemed, but I have never met with it in Ceylon. The local demand, together with that for the India market, absorbs the whole of the supply, but if inquiry were made for it, in proper quarters, a surplus would soon be created. The increase of Gingelly seed is sixty-fold, and the price on the spot about 2s 6d per bushel of 45 lb. at the commencement of the season. †

Cardole.—This is the oil contained in the pericarp or inter shell of the "Caju" nut, *Anacardium Occidentale*. It is of a deep black color, with a nauseous smell, and is extremely acrid, raising blisters almost immediately. Its properties are known in England, where it is much valued. The native method of extracting it is very effective, but too costly in a country where fuel costs little or nothing. The husks are put into a chatty, the mouth of which is covered with the net-like substance procured from the young coconut-tree, and an empty chatty being in like manner secured, the two are put into a hole in the ground, the full chatty being placed with the mouth downwards on the top of the empty one. Earth is then heaped over them, and a large fire kindled on the surface, which is kept up for a dozen hours or so, until every drop of oil has filtered into the lower vessel. Five thousand three hundred nuts gave nearly 8 lb. of oil in a recent experiment, and with a simple contrivance for removing the outer husk, and a less expensive method of making the oil, the manufacture might be made a source of much profit.

Ricinus Communis.—The castor-oil seed abounds throughout the country, many abandoned clearings being entirely covered with it, but it is only used to produce a nearly black rancid oil, which is sold in the bazaars at a much higher price than the best refined oil would cost, imported from India. Over the vast extent of waste lands, there are numerous tracts where the seeds might be scattered towards the close of the rains, and as the tree requires no care, a highly profitable cultivation might be set on foot at a mere nominal outlay. Efficient machinery for extracting the oil would cost but little; and where the first expense was an object, a careful process of boiling would produce a pure and almost colorless oil, quite equal in quality. As

castor oil, when the price falls in the home markets to £30 per ton, can be sold in any quantity for soap making, there need be no fear of an excess of production.*

Margosa.—Thousands of tons of this seed could be annually collected, growing as it does nearly in all parts of the island, but except at Jaffna where it is largely procurable in the North-East Monsoon, it is doubtful if more than a handful or two is gathered elsewhere, and that for merely local use. The oil is seldom to be had in the bazaars for less than a shilling a pound, and its use is confined merely to the treatment of sores and cutaneous affections. Medical men who have studied the properties of margosa oil assert that it is invaluable in cases of consumption, its curative effects being quite equal to those of Cod Liver Oil. The nauseous smell makes it an object of dislike to the owners of native mills, who refuse to make the oil, on the ground that it would be almost impossible to make their checkos or pug mills sweet again. As an article of export it can only be made to pay by the use of machinery which might be very advantageously employed in the manufacture.

Bassia Longifolia.—This seed, the *Mi* of the Singhalese, grows extensively in the districts of the Northern and Central Provinces, and is everywhere carefully collected and sold at rates which afford the villagers good profit. Its local uses are confined to burning in lamps, and the anointing of the body with the oil cake which softens the skin, and is thought to have medicinal value, but in commerce it is reckoned the first of the vegetable oils for the manufacture of soap. It is exported from Jaffna to some extent, but the demand for local consumption absorbs nearly the whole of the local supply.

Jatropha Curcas.—Caat Aamunak.—This small tree, which is universally planted as a hedge in the North-Western Province, produces in great abundance a nut which has powerful purgative properties. It makes an oil of a yellow colour, very pure and limpid, and could be made an article of considerable commercial value.

Molabodee.—The wild nutmeg yields to pressure and boiling a very pure description of vegetable butter, but it is not found in sufficient abundance to make it worth the attention of merchants.

Murunga.—The oil from the seeds of this tree is the very purest known. Watchmakers use it under the name of the *Oil of Ben*, but though it would always command a very high price in the home markets, and grows tolerably abundant, the use of the legumes, as a favorite article of food, will always hinder the seeds from becoming an article of export.

In India the flowers of the *Bassia Latifolia* are used to make an intoxicating drink, but in Ceylon the seeds only are occasionally used. The oil which they yield is of very good quality, and if the jungles were properly searched, a large quantity might be obtained.

Kon.—The produce of the Ceylon Oak is a small seed yielding a light-colored oil, suitable for burning in lamps. The tree is not a very abundant one, but it gives a plentiful crop of seeds and would pay coolies well for collection.

Croton Tiglium. Neervalum Cottay.—Qualities of Croton oil are well known, and as the tree requires no care to bring up, and the oil is worth on the average 3s per lb., no greater proof of the apathy of the Singhalese is needed than the statement of the fact that it is never exported raw from Ceylon. †

* The export of coconut oil from Ceylon in 1888 was 364,116 cwt. valued at R4,531,223.—Ed.

† Gingelly poonac is largely imported from India. The Export from Ceylon of gingelly seed in 1888 was 14,050 bushels, valued at R32,800.—Ed.

* Both castor oil and cake are imported from India, where the plant is largely cultivated. The price of castor-oil now is from 3d to 4½d per oz.—Ed.

† The price of croton seed now is from 15s. to 20s. per cwt.—Ed.

Caju.—The oil expressed from the Cashew nut is far superior in purity, color and sweetness of taste to the best Olive oil. The seed is procurable in large quantities in the Negombo and other districts, where it grows wild in the jungle and is widely cultivated as well. No oil has ever been made in the island, the kernels being considered a great delicacy by the people.

Serthia Indica.—Semmanathy.—This oil is procured by the destructive distillation of the Semmanathy or Aghib, the wood of which gives out a pleasant but faint perfume, and is sometimes taken for sandalwood. The odour is due, to the presence of the oil, which is said to have antiseptic qualities, and is doubtless worth a close examination. The tree which never grows to a large size, is found abundantly in the country lying between Chilaw and Calpenty, and on the Eastern coast in the Batticaloa jungles.

TANNING SUBSTANCES.

Ceylon is peculiarly rich in materials suitable to the use of the tanner, and if the native leather dressers knew how to prepare skins properly, the export of tanned hides might make a good figure in the Customs returns. The barbarous custom of branding cattle renders the skins so treated of no value for the home market, but buffalo hides and deer skins are to be had in abundance, together with a certain proportion of clean hides, so that there is no want of raw material. The process of tanning is not very recondite, and a little attention paid to the improvement of native methods would be of great benefit to those concerned.

The barks of the *Rhizophora Mangle* (Kadol), *Cassia Auriculata* (Poomasarie), and *Anacardium Occidentale* (Caju), are solely employed for tanning in Ceylon. The first-named contains the greatest proportion of tannin, but it would not find favor in England on account of the red color which it imparts to the hides. This objection, however, ought not to apply to any great extent, as there is a vast quantity of leather manufactured for purposes where the mere color of it is of no moment whatever. The Kadol or Mangrove grows in abundance on the banks of the creeks and swampy grounds in various parts of the island.

The *Cassia Auriculata* furnishes a light-colored tanning material, which if exported in quantity would command a ready sale. The same may be said of the *Anacardium*, which however has a much smaller percentage of tannin, a disadvantage which is neutralised to a certain extent by the abundance of the tree, which covers a large extent of ground in the Southern and Western Provinces. In all cases where barks are collected for export, they should be boiled down to extracts, care being taken not to employ vessels made of iron in the operation. The new substance which I have been able to discover in the class of astringents as being of use to the tanner, are the *Memeylon Tinctorium* (Cassa leaf), the barks of *Aereya Arborea* (Kahata), *Terminalia Alata* (Kumbuk), and the *Cathartocarpus Fistula* (Sinienda). The first-named article tans skin rapidly, producing a light yellow color, with considerable bloom upon it. The *Aereya Arborea* which forms jungles in many parts of the Central Province and elsewhere contains more tannin even than *Cathartocarpus* which yields above half its weight of astringent matter. When converted into an extract, it falls into powder, which is not the case with the *Terminalia*, which forms a solid coherent substance and will doubtless find favor in the tanyards. It abounds on the banks of streams in the North-Western Province, and attains the greatest size of all the timber trees in the island. The whole of the articles mentioned in this paragraph

are of much importance in a commercial point of view, and are to be had in any quantity.

The *Acacia Catechu* is of course well known as affording the famous Pegu "Cutch," but its existence in Ceylon was wholly unsuspected until November last, when I found it in a jungle at the southern end of Patchilapallai in the Jaffna district. I could never discover that it extended beyond a patch of four or five miles in extent, and Mr. Dyke, whose acquaintance with the *Flora* of his district may be considered almost perfect, had never met with it elsewhere. The presumption, however, is that a diligent search would be more successful, and in that case the inhabitants of the northern portions of the Peninsula would find it to their interest to prepare the Cutch for local consumption, bringing as it does a high price in the bazaars. There is no skill required in the way of manufacture. The tree must be cut down and converted into chips, which are boiled for many hours in earthen vessels. A second boiling of the wood follows, and the two waters are then mixed and boiled down to an extract, which is poured into moulds and left to dry slowly. Cutch, which is often mistaken for Gambier or Terra Japonica, is always worth about 30 per cent more in the home market, and contains in its purest state 53 per cent of tan.

The *Embryopteris Glutinifera*, Timbiri of the Singhalese, has never been employed to convert skin into leather, but it is universally employed to tan fishermen's nets, and the gum which exudes from it contains no less than 70 per cent of tannin, the largest proportion known to exist in any vegetable substance. It contains an oil, a gum and a brown dye, and growing as the tree does in inexhaustible profusion, the extract made from it would be a source of abundant profit.

To ascertain the existence of tannic acid in any vegetable material, the best mode to adopt is to take a piece of thin skin, and having carefully cleaned and weighed it, to steep it in an infusion of the article under experiment and apply a gentle heat. Perhaps in the course of a few hours the tannin will have penetrated through all the pores of the skin and converted it into leather, when it is only necessary to dry it, and on weighing it a second time, the increase of specific gravity will be the measure of the amount of tannin absorbed. A quicker method than the above is within reach of those who have chemicals at hand:—Make an infusion of the supposed tanning material and add a few grains of sulphate of quinine. Pour a few drops of sulphuric acid, when the tannin will fall to the bottom in the form of a grey precipitate. To get a knowledge of the comparative amount of tannin, evaporate the solution of the material to dryness and weigh the grey precipitate against that formed by an equal quantity of Cutch, "the Cashouttie" of the bazaars. If it nearly approaches the outturn of the latter, it may be relied upon as worth further notice and investigation.

FIBRES.

Almost every known kind of fibre flourishes in the island, the *Urtica Nivea* or Rhea perhaps excepted. The soil and climate are peculiarly fitted for their growth, so that if the experiments for utilising those valuable substances can ever succeed, Ceylon affords the best chance of achieving such a result. With an increase of population it might be made to produce cotton largely of an excellent quality.

Cotton has always been raised in the island to a certain extent, but at one time it formed the chief staple of the Jaffna Peninsula which is well suited for its growth, as there are several months in the year during which no rain falls, and the work of picking can be carried on without loss or difficulty. It is

still grown in chenas in the Anarajapura district. but only for local consumption, neither the quality nor the quantity of it offering any inducement to extend the cultivation: In no place is it sown regularly; a handful of seed is thrown broadcast over the clearing together with one or other of the pulses, and the cotton comes up like a weed. It is difficult under such circumstances to form an idea of the yield per acre, but it does not exceed five of clean cotton. It is not therefore a favorite culture. Gingelly seed which is always saleable at paying rates, is preferred to it in the majority of instances, and in Jafna the people mainly devote themselves to the cultivation of tobacco, and could scarcely be persuaded to abandon it in favor of cotton. For the reason hinted at above, cotton cannot be expected to flourish in the Central and Western Provinces. Heavy showers of rain would interfere sadly with the picking, and these may fall at any season of the year. But there are districts where this grave objection does not apply. We owe our knowledge of its capabilities in this respect entirely to Mr. T. Power, Assistant Government Agent at Ratnapoora, who writes on this subject as follows:—

“The cotton I send is from Native seed and also from Sea Island. The garden is thriving magnificently; nothing could look better than the plants and pods. The climate here appears quite the thing for cotton,* and my plants are now giving their third crop within the year.”

If a supply of labour could at all times be depended upon, there is little doubt that the tract of country described by Mr. Power might be made eminently productive as a cotton tract, but unless it pays better than other crops, the resident cultivators will not grow it, and there is always that difficulty in the distance. By the aid of bounties or the influence of headmen, a cultivation can be got up of any kind of produce, but upon a large scale no crops will be raised except those which are most profitable. A few model farms established in various parts of the island and cultivated after a fashion which could be imitated by the bulk of the population might be successful in inducing an extended growth of cotton, but nothing should be done by the European which the Singhalese could not easily follow. It is not likely that Ceylon will ever be a great cotton growing country, but it may by judicious management be made to export a considerable amount of it.†

A far more hopeful prospect exists with reference to wild fibrous plants, such as the *Sansevieria Zeylanica*, Niyanda of the Singhalese and Marool of the Tamil, the Aloe, Agave, Pineapple, Plantain and *Asclepia Gigantea*. There are literally millions of tons of these plants scattered over the face of the island. They grow in any soil, the sand or the swamp seems to afford equal nutriment to them, and if one cared to make a plantation of them, a limitless supply of fibre could be obtained. But the drawback to the production of these exquisite threads have hitherto been such as to render their existence of no practical value except to the fishermen and the villagers who require the occasional use of twine and rope. The labour needful to extract the fibres is nothing of course to these persons, so far as the supply of their own wants is concerned, but if they are employed in the work at daily wages, or asked to furnish fibres to the merchant, the cost of production is out of all proportion to the value of

the articles. It would take ten hours of persevering labour to enable a man to make 8 ounces of fibre, which if he were paid only 6d. per day would thus cost in the village nearly £60 per ton. In no part of the East, however densely populated, could fibres be prepared and sold at a profit in the only way that hand labour can turn them out fit for the weaver's loom, for if we halve the rate of wages, the cost would still be too dear. By adopting the retting process, as it is termed, steeping the fibres in water, and letting them remain submerged till the pulpy substance is quite decomposed, a large quantity of fibre can be beaten out in a day, but it is harsh and woody, and would have to be submitted to chemical processes before it could possibly be made fit for conversion into cloth. As material for cordage and manufacture of paper, fibres prepared in this way, lose but little of their utility.

It must always be borne in mind that in estimating the value of fibres as textile material the quantity to be obtained is the first matter for consideration. Small parcels are literally worthless, except as objects of curiosity. Weaving is done universally by machinery, and you cannot work up a new fibre with the machines that have been contrived for those in common use. The first inquiry which the manufacturer would make on being shewn a sample of it would be as to the prospects of an abundant supply. If he saw his way clear in this respect, he might feel inclined to alter his machinery to suit it, but not otherwise. It is only as paper material that small exports could be made available. At least hundreds of tons must go forward of any material meant to be woven in order to make it saleable at its true value, and as yet there are no signs of such a result in the case of succulent plants as those are termed, the fibres of which form the body instead of the bark. The reason will be readily comprehended when we state that the average weight of fibres derived from the plantain and *Sansevieria* is but 4 per cent. An ordinary plantain tree yields about 40 ounces of fibre, so that it would take forty-five trees to furnish a cwt. The labour involved in cutting and transporting this vast quantity of useless material is so great, that it renders even machinery worked by steam of no practical value, except under very peculiar circumstances. It would require nearly two acres to give a ton of fibre at one cutting and the manipulation of a thousand trees, and nowhere do we find such tracts of the plants growing wild as would supply a factory. A cultivation of the Marool on a scientific system, the fibres being extracted by Benke's machines would yield magnificent results. The Marool fibres obtained from the fresh plant are scarcely inferior to silk in beauty and softness, and would command very high prices. So would those of the Pineapple, and also there can be no question as to the quantity of fibre that could be grown, and the permanence of the demand for it, if it could be had to any amount. The sole problem to be solved is the invention of a cheap and efficient method of extracting the fibre. If a simple machine can be found, that is within the reach of village skill to construct it, and present means to buy it, there is no saying to what extent fibres may not be ultimately forthcoming. Every village hut is overshadowed with its plantain tree, and if that can be turned to account for fibre, as well as fruit, the relief to the cotton market would be of the greatest possible value. I have reason to believe that a French invention which was rewarded with a prize at the Exposition in Paris, will supply what is wanted and shall be able to test its usefulness, the result of the experiment shall be duly communicated to the Committee. Coconut fibre is a product of increasing value as an article of export, but its uses are not likely

* The climate of Ratnapura is one of the rainiest in the island.—Ed.

† The establishment of a cotton mill at Colombo alters the conditions wholly. The export from Ceylon of Cotton wool in 1888 is given as 2,320 cwt., valued at R56,919.—Ed.

to be widely extended so as to create an advance in price in the home markets. The manufacture has been greatly improved by the application of machinery, but unless the coir could be made at least as cheaply by steam power as by hand, there can be no gain in the adoption of the costly process. The superior brightness and evenness of appearance is but of little value in the estimation of the manufacturer who finds in the material produced by the labour of women and children, an article good enough for his wants. If coir could be converted into a substitute for twine or whipcord or woven into cloth, its worth would of course be greatly enhanced, but it is a harsh brittle fibre, and breaks shortly off if sharp turns are taken with it. It will not pay then to employ steam engines in the manufacture of an article like coir which can be had in Jaffna at 4s. 6d. per cwt., but a machine invented by Mr. Thomas of the Marandahn Iron Works is likely to be of much service on coconut estates. It is worked by hand, and can turn out, it is said, one cwt daily, which is worth on an average of distances throughout the island at least ten shillings. The nut is only steeped in water for a few hours, and the product is of the first quality in point of appearance. Coir fibre averages about 20s. per cwt. in the home market.*

The long fibres of the *Caryota Urens* (Kitool), are held in much esteem as a substitute for whalebone in brush making. They are procurable to a considerable extent in the hilly districts, and are worth on the average about 9d per lb.†

The fibre question deserves the utmost attention on the part of those who are charged with the duty of investigating and developing the resources of the island.

STARCHES.

ARROWROOT (*Maranta Arundinacea*).—This plant grows to perfection in almost every part of the island, but gives the largest yield perhaps in the hilly districts. The cultivation exactly resembles that of the potato. The ground is either ploughed or dug in trenches, and the roots or suckers, for either will propagate the plant, are set in rows two feet apart, with a distance of say twelve inches between each plant. As it comes up, the earth should be gathered round it, and if planted in the dry season, it will require watering for a couple of months. The soil should be weeded, and the leaves pruned if they grow too luxuriantly. The crop is about seven months coming to maturity, and the yield depends upon the care bestowed on the cultivation and the richness of the soil. A loose friable earth is the best adapted for the purpose. At Borella, near Colombo, the outturn is about 21 cwt. per acre, but in the West Indies it is as much as six or eight tons, and there is no doubt that at least double the first-named amount could be obtained as an average in this island. The labour when entirely performed by hand amounts to about 70 days' work per acre, and the price paid for the roots at present is 6s per cwt.; allowing the whole business of cultivation to be carried on by adult laborers, paid at the rate of 7½d. per diem, the profit to the owner of the soil is above £4 per acre.

The manufacture as carried on in Ceylon is an affair of the simplest kind. A roller of about eight inches in diameter, and about two feet in length, is fixed against a piece of wood, which is secured by a couple of uprights. The roller is covered with a

sheet of tin, pierced with holes like a nutmeg grater, and it is set in motion by a wheel just like that of the native turner which communicates with a smaller one on the spindle of the roller. A small space is left between the roller and the board, and the roots having first been washed and peeled with the fingers are chopped into it, a little water, being occasionally used. As the roller revolves, the rasped root falls into a trough placed below it, and is carried to another trough where it receives a first washing. The woolly fibre which floats on the top of the starch is then taken off, and the latter is put into a trough lined with lead, where it receives successive washings until the last water comes off colorless. The arrowroot is then found at the bottom in the shape of a solid white substance. A clean cloth pressed upon it absorbs the remaining surface moisture, and it can then be cut with a wooden or copper knife and laid in the sun to dry. When the water is perfectly expelled, the lumps break into small pieces, and the starch is fit for the market. Great care should be taken not to pack it whilst in a damp state, and for long voyages it should be put up in tins. The local selling price is at present 1s. per lb., but 9d. is the wholesale rate. The arrowroot exported from Ceylon is said to be equal if not superior to the best kinds from the West Indies.

Six men can manufacture a hundredweight of arrowroot in a day, with the aid of the very simple machinery above described, to do which they have to manipulate above 7 cwt. of roots, the yield of starch being 15 per cent. The cost of the raw material being £2 2s, labour 3s 9d, and the price of arrowroot being 9d per lb., the manufacturer's profit per cwt. is £1 18s 3d, or allowing for contingencies say £1 15s. No bad return for the slender capital required in the business.

BITTER CASSAVA (*Jatropha Manihot*).—This plant, which grows as a weed nearly over the whole island, furnishes the well-known tapioca and cassava of commerce. The roots are treated for the starch exactly the same way as the arrowroot, but to make tapioca, the meal is placed before thoroughly dried upon hot plates, when it granulates and takes the shape in which it is found in the market. The cassava is the starch prepared throughout like arrowroot. But the water which comes off the first washing is an active poison, and the starch is only fit for food, when the whole moisture has been driven off and the meal has been for some time exposed to fire or the sun's rays. No use is made in Ceylon of this dangerous liquid, but when boiled down to the consistence of molasses, it forms, strange to say, one of the most valuable bases of sauce, and is the famous "Casareep" of the West Indies.

TAPIOCA is an article of great value as food, its nutritive qualities as compared with wheat being, it is said, 6 to 1. In Demerara an acre of it has yielded 25 tons, but it has not been cultivated in Ceylon as yet, except for fences. Two-fifths of that yield would give a ton of starch worth to the grower, at the rate paid for the roots in Colombo no less than £40. One-fourth of that sum would pay him well, for the plant requires no more cultivation or care than the castor tree, to which it bears a strong resemblance; and in that case, the manufacturer purchasing his raw material at the rate of 10s per cwt. of starch, paying 5s for labour, and selling the prepared article at 6d per lb. would clear 41s per cwt.* The local selling price is at present 1s 3d per lb.*

PANNAN NILLINGOES.—This is the Tamil name of the tubers which spring from the fruit of the Palmyra tree, when planted in the ground and left

* The price of coir fibre now is from £20 to £32 per ton. The export from Ceylon in 1888 was 22,090 cwt.—ED.

† The export of kital fibre from Ceylon in 1888 was 1,703 cwt., valued at R46,074.—ED.

* A considerable quantity of the roots grown at Henara-goda did not pay the cost of carriage to Colombo.—ED.

there for about six months. If suffered to remain, it would of course spring up into a tree, but the natives pluck it, and by scraping and washing convert it into a favourite article of food. When treated by the process for making arrowroot, it produces a starch even superior to it, and it can be made at Jaffna and Calpentyne where palmyra trees abound for about 3d per lb.

YAMS.—These are most abundant, and in the more elevated parts of the island attain a great size. There is a variety which has the exact flavor of the potato when carefully boiled. The latter root grows well in Nuera Ellia, from whence it finds its way to all the bazaars, and the sweet potato is very common. Starch in great variety can be procured from all the tribe by the process heretofore described, and would pay very well. Immense quantities of potato starch are used in the weaving mills at home under the name of Dextrine or British gum, a substance formed by roasting the starch. The average price is about £40 per ton.

The day must come when the manufacture of starches for which Ceylon offers such great facilities will meet with the attention that it deserves from enterprising persons. It requires so little capital, and the processes are so simple, that many may be expected to devote their time to it.

CAOUTCHOUC AND ITS SUBSTITUTES.

The tree which produces mainly the Caoutchouc of commerce (*Ficus Elastica*) is not indigenous to Ceylon, though magnificent specimens of it are to be seen at Peradenia, but almost any quantity of milky viscid fluid, bearing the greatest resemblance to it can be procured from the different varieties of *Euphorbiaceæ* which abound in the island. The *Eucocaria Agallochum*, Tilli of the Tamils, and the *Artocarpus Integrifolia* (Jak), yield a juice in great abundance, which might easily be mistaken for Caoutchouc.

But the characteristics in each case are the same: on being plunged into boiling water, the fluid rapidly acquires consistence, draws out in threads like the genuine substance, and in that state will receive and retain impressions, but as soon as it gets cold, the pliability is lost, and it breaks, if you try to draw it into threads or to increase its tenuity. It will rub out pencil marks, and whenever submitted anew to the action of the hot water it exhibits the properties of Caoutchouc. The question of its value as a waterproofing material, or as a substitute for Caoutchouc, in some of the numerous uses to which the latter is applied, is well worth the attention of the practical chemist. A good method of sending the milk home for examination and report would be to apply it with a brush, as it is drawn from the tree to the inside of a clean case or cask. When the first layer was dry, another should be laid on, and in this way a mass of solid milk would be in time accumulated, not liable to fermentation or damage from keeping. If it could be turned to account, the supply might be depended upon as being perfectly inexhaustible.

TOBACCO.

The article of Tobacco is strangely neglected by our countrymen in Ceylon, considering the extent to which it is grown, the excellence of its quality in the green leaf, and the vast impetus that might be given to the cultivation, were foreign markets opened for it. A very large quantity is raised in Jaffna, nearly the whole of which goes to Travancore, where the Raja monopolises the

sale of the article. The consumption of Tobacco by the natives is very large, and very little of it comes from India, indeed so much is the Kaymel growth prized, that the leaves sell at 8s or 10s per lb. When made up into cigars, it is frequently preferred by Europeans to Manillas, and there is a capital story told by a distinguished person who carried home a quantity and requested one of the first tobacconists in London to smoke a few of them, and say what he thought of the flavor of the new importation. In due time the report was made, the cigars were pronounced to be "good smoking, but not at all fit for the English market. Oh no, there was such a strong flavor of Otto of Rose about them." As the laughing querist informed the shopkeeper, the cigars cost less than a farthing each, which left but a small margin to cover the cost of the Otto of Roses.

There is of course much difference in the strength, and flavor of the tobacco grown in various districts; but the best and the worst are equally ill dealt with, from the want of a method of curing the plant. All that the cultivator does to fit his tobacco for sale, is to hang up the leaves to dry, and it is frequently seen in the merchants' godown, mottled with green, brown and yellow colors. The true aroma of the plant is never developed, for that can only be brought out by employing pressure upon large quantities of heaped leaves. The proper method of curing the leaf is as follows:—

The leaves when cut down should be tied together, at the foot stalks, and hung across a line or pole to dry in the shade, care being taken to turn them from time to time, and to exclude moisture. When they are perfectly dry, they should be taken down and placed in a heap, the mass being at least a ton in weight. Heavy pressure must then be applied and continued for about ten days or a fortnight. The effect of this process is to induce a species of fermentation which permeates the whole heap, renders the leaves of a uniform color throughout, and evolves as well a certain volatile essence, which gives almost a new flavor to the tobacco. Considering that the average price of Jaffna Tobacco is very low, and that the demand for the cured article never ceases, it is clearly one of the safest, as it would certainly be one of the cheapest experiments, to purchase a sufficient quantity of the leaf at the proper season of the year, and to ascertain if the Ceylon article would really be made to compete with foreign growths. It is asserted by persons, whose opinions are entitled to respect, that it is only in the curing and subsequent manufacture that Manilla Tobacco is superior to our Island samples; and if this be correct, a very great addition might be made to the wealth of the Colony. All that is necessary, in the first instance, is to guard against the receipt of badly-dried leaves, or to buy them freshly cut. The manufacture could not fail to be a paying one.*

DRUGS AND MEDICINAL SUBSTANCES.

A vast number of articles recognised in the Pharmacopœia are to be found in Ceylon, and may generally be had at cheap rates, always supposing that there is no dearth of population where they grow. Every variety of *Strychnos*, including of course the *Nux Vomica*, is to be met with in abundance, and throughout the Central and North-

* In 1888 Ceylon exported 57,282 cwt. of tobacco, valued at R1,236,307.—Ed.

Western Provinces.* The *Hemidesmus Indicus* (*Nauware*) is a common weed. This plant is considered by the faculty to be even superior to Jamaica Sarsaparilla, of which it has the exact scent and flavor, and whereas that ranges in value from 2s to 3s per lb., any quantity of the Ceylon drug could be gathered for a penny a pound. The root of the *Sansevieria* is an excellent substitute for Ipecacuanha. The Margosa oil is one of the very best applications for ulcers, and the virtues of Croton and Castor oils are well known. Under the head of tanning substances I have described a number of astringents which would prove of great utility for medical purposes.

The Singhalese have a great number of medical agents in use, the value of which is either unknown to, or wholly neglected by European men of science. They possess undoubted antidotes for snakebites, many remedies for fever, and there is every reason to believe that the terrible malady, hydrophobia is within reach of their curative powers. I have taken great pains to ascertain the foundation for this belief, which is universal among the people, and was obliged to acquiesce in the common opinion, always bearing in mind that there is great difficulty in finding out whether persons bitten by dogs, labouring under supposed rabies, have really taken the deadly poison into their system. The instances of reported cure are scattered over the whole country inhabited by Singhalese. The Tamils never pretend to a knowledge of the remedy. The symptoms produced by administration of the medicine are always described in nearly the same words, and I have found a constant agreement in the statement, that although, a cure is certain, at any period between the occurrence of the bite and the day when hydrophobia makes its appearance, the remedy is wholly powerless in that last stage of the disorder. The patient when taken in hand in good time, has a preparation given to him which induces delirium with all the signs that follow the administration of Stramonium (*Datura*), and it is certain that this powerful drug forms part of the medicine given, and if I might venture to hint a belief on the subject it would be that the *Datura* is the real curative agent. I could say much in support of this theory, but refrain from doing so, as no opinion can have any possible weight in the matter, and one is entitled to believe, that enough has been said already, to call the attention of scientific persons to the consideration of it.

There is a tree growing in the Patchalapala district, in the Northern Province, the Tamil name of which is Elamboreka, literally translated "bone-setter." The medicinal properties reside in the bark, and the native doctors are accustomed to apply the pounded drug in the shape of poultice to a broken limb, for the space of about twenty minutes, or as they calculate for the time a pot of rice takes to boil, when it is removed and the limb bound up in the confident expectation that the several parts will unite without further trouble. Fabulous stories are told, as a matter of course, of the virtues of this remedy, but a case came under my own observation which may as well be stated. A Singhalese, aged about fifty, was brought to Mr. Simon Casie Chitty, late Judge of Chilaw, having been picked up on the roadside where he was left by robbers. They had beaten him with sticks until his arm was smashed from shoulder to wrist, and the Judge was for calling in at once the Sub-Assistant Surgeon, but the men declined the offer with somewhat of scorn. He was, he said, a *Vederale* (doctor) himself and

could set his arm to right. Fortunately for him there happened to be a solitary Elamboreka tree in the jail compound, and he had the bark of it applied in the manner above detailed. It seemed impossible that he could escape amputation, but two months afterwards he was in the field, superintending his laborers, with a sound and apparently strong limb. For the truth of this statement I can vouch, having seen the battered arm, and also seen the man after recovery.

The *Coccinium Frustratum* (*beniwelle*) is a creeper which grows in vast abundance in the Western and Central Provinces, is an excellent febrifuge, and was warmly recommended as such by the late Dr. Elliott. As a bitter tonic it is serviceable and pleasant, and could be converted into an extract for the smallest trifle of cost. But there are so many medicinal substances worth enquiry and analysis, that it is idle to attempt to enumerate them. Were the Government to engage a competent person to report upon them, they would do great service to the colony, and perhaps even to mankind at large.

OIL OF EUCALYPTUS.—A correspondent writes:—"Mr. S. G. Wallace, of 'West End,' Ootacamund, has for some time past been engaged in conducting a series of experiments with the oil of eucalyptus. The oil is extracted from the eucalyptus globulus which grows luxuriantly on the Nelgherry Hills, and is said to possess great medicinal virtues. It is largely used in some of the hill tracts in Northern India, and is gradually coming into use in Southern India. It is specially effective in cases of rheumatism, bronchitis, &c., and is a good deodorant and disinfectant. The experiments made with it by Mr. Wallace have been attended with very considerable success, and the oil is said to have effected some marvellous cures in cases of chronic dysentery. The oil has a pleasant taste and odour, and is a powerful tonic. Mr. Wallace's labours in this matter are deserving of encouragement."—*Madras Mail*, 29th August.

ALARGE BEAUTIFUL LOCUST was sent to us a few days ago from "the field" by Mr. Scott Barber, who says he has never seen one before in Ceylon. Mr. Staniforth Green at once identifies it as No. 23 (*Phymateus punctatus*) in our edition of "Nietner's Enemies of the Coffee Tree." We quote as follows:—
This is the large, well-known, beautiful locust with the scarlet abdomen, yellow and bronze above, which seems to attack all agricultural produce that comes its way. It does not habitually attack the coffee tree, but does so occasionally, and I speak from experience when I state that its ravages are very annoying. A swarm of them settled upon a field of one year old coffee and gnawed the bark off the stems. The consequence was that the growth of the tree was checked in the upper part, and that a multitude of unsightly shoots were thrown out by the lower; eventually the top broke off, or was cut off, and the tree remained disfigured for the rest of its existence. There were at least fifteen per cent of the trees thus injured. I remember seeing a coconut plantation at Negombo infested with these locusts, the enormous leaves of the trees bending under their weight, and presented mere skeletons—everything but the ribs having been devoured. A great many of the locusts had dropped off upon the illook-grass (*Sacch. Koenigii* Reitz) which grew beneath, but they would not touch this. In fact, I have never seen them to eat any but cultivated plants or trees. At Tangalla I have known them to destroy tobacco plantations; and a couple of years ago I was addressed by the Government Agent, Kandy, with reference to the injury the grain crops of the natives in Matale were then suffering from these locusts. Fortunately, this seems the only species of locust that does any real injury in Ceylon, and this injury is in importance not to be compared with that done by other species in other countries.—See Kirby and Spence's *Introd. to Ent.* for details on this subject. The larvæ and pupæ are equally destructive as the perfect insects.

* The price of nux vomica now in the home market is from 9s to 11s per cwt.—Ed.

HILLCOUNTRY PLANTING REPORT.

DODGES OF THE COOLY TRAFFICKERS—THE REVIVAL OF COFFEE AND PLANTING UNDER SHADE—UVA FOR TOBACCO—COTTON—RAILWAY STATIONS AS ADVERTISING MEDIUMS FOR INTOXICANTS.

20th August 1889.

The traffickers in COOLIES have many dodges. We are all acquainted with the system of buying and selling which goes on among kanganyes, and which is one of the principal reasons for the fluctuating nature of our labour force. A cooly disappears, and you are told that he has bolted and taken one or two others with him. If you press for the reason why he left, it is because he disliked the master or the estate, and that to insist upon a task ere a full name was given, was too much for his proud spirit, so rather than endure it he had revolted and fled. An opportunity of this kind to have "a dig" at discipline, and cast discredit on the Western notion, that for a fair day's wage a fair day's work should be given, is much too precious to be neglected, but he is a very inexperienced fellow indeed who is taken in with that kind of thing. You don't take long to learn the signs which indicate whether the deserters have decamped with the sanction of the kangani, or without it. When it is a real case of bolt, and the kangani is left without a settlement having been made, the daring act evokes a fine active spirit: the kangani simply overflows with energy, wants letters, wants warrants, institutes all kinds of inquiry, and the lapse of time has little effect on his burning desire to recapture the runaway. He laughs at distance, scorns fatigue, and the disappointment of an unsuccessful hunt whets rather than damps his ardour. The man who has been "squared" does not do this: although for politic reasons he may try to get up an enthusiastic indignation, yet it's such a hollow affair, that it burns itself out in the very presence of his employer, and the man must be blind who fails to see that an understanding had been come to.

Now, however, there is "another Richard in the field," and to the bartering kangani there has to be added the native hotelkeeper. This worthy seems to be winning his way into the affections of the cooly—especially the wandering portion—for when the waist-cloth has been tightened, so that the gnawings of hunger may be less keenly felt, the man who will give a meal on credit, and a mat to sleep on, comes to be regarded as a benefactor. Of course the native hotelkeeper has his own objects in view. Kanganyes, who have got advances for labour, come in to his hotel as well as others, and as the labour need is pressing, and to send to the Coast, then, out of the question, the hotelkeeper mentions the fact that several stray coolies have been staying with him for a week or ten days now, and if the kangani will give R1 a head, and settle what they owe for food, he will induce them to go with him. This takes at once, and the bargain is struck. A two days' stay at the native hotel works out seven at least, by those marvellous rules of arithmetic which apply almost solely in coolies' affairs, and not to speak of profit as a labour agent, the native hotelkeeper scores in his legitimate calling albeit in an illegitimate way. But when he parts with the coolies he has been harbouring he gives them a little advice. And it is this:—If they are not satisfied with the kangani or the estate, they are going to, just come back to him, and he will keep them until they get employment elsewhere! By this means he creates for himself a steady income, and the native hotel is becoming recognized among

our kanganyes as a recruiting ground where a *pro tem* supply of labour can be got, and at not a very high cost either. A kangani who wants to deal fairly would be suspicious of the "*shothekaddai ol*," but some are simple, and some have not a very high sense of honour, and so the native hotelkeeper plays upon their weaknesses, and in a manner which is highly profitable to himself.

The revival of COFFEE, and with it the downfall of bug and leaf-disease, is becoming, like the big gooseberry in the dull season at home, the subject of a periodical paragraph. Is it true, however, or is it but that the wish is father of the thought? Coffee about this is at present sadly stricken with leaf-disease, up to the best that was ever produced; but bug, I am glad to say, is not by any means rampant.

The men who are going in for a renewed trial of COFFEE UNDER SHADE are getting more and more impressed with the belief that when the shade tree is a *ficus*—400 to the acre—the chances of success are very much increased. I saw some coffee the other day, growing under one of those large trees, and for vigour and healthiness it would have matched anything to be seen in the "days of old." If an extensive acreage would do as well as the patch I refer to, the revival of coffee in Ceylon would be an assured fact. Later on we will doubtless learn the outcome of this new combination.

TOBACCO growers in their search for land have invaded the benighted Province of Uva, and I hear that applications for large acreages have been made to the Government Agent there. If the company we heard of, that was to establish depôts all over the country for the purchase of tobacco in the green state, were to move now, there is little doubt, but that the growing of "the fragrant weed" would be taken up very extensively. It is the favourite among the newest products. "Cotton"! said a man to me, who is ever ready to pioneer,—"*Cotton!* why it is n't 'a patch' on tobacco, and I have tried both."

One of the Buddhist papers is protesting and drawing attention to the fact that the Government of Ceylon has of late allowed its railway stations to be used as advertising mediums for INTOXICATING DRINKS. From Nanuoya to Kalutara, there is hardly a station, where some whiskey or another is not flauntingly placarded and brought before the traveller's notice to the offence of those who would desire to see the people of Ceylon a temperate people and unacquainted with such drinks.

All my sympathies are with the Buddhist writer, and it must have been through inadvertency that the Government has allowed part of its property to be abused in this way. Whiskey drinking among the natives could lead to nothing but evil; and that the Powers-that-be, whose duty it is to do all they can to promote the elevation of the people, should be indirectly the means of promoting the reverse, is far from creditable. Has the Government no fear of Mr. Caine or Mr. Samuel Smith before its eyes? for it would be an easy matter to get either of those gentlemen in their place in the House of Commons to inquire why the Government of Ceylon should prostitute its property to further the consumption of an article which, if the natives indulged in, would lead only to disastrous results, or be to them as an abiding curse.

PEPPERCORN.

DRY GRAIN AS FOOD.—Mr. Alfred Driberg in an article on chena cultivation shortly to appear states that an opinion prevails regarding dry grains (chiefly kurukkan and other millets grown without irrigation) that such grains are not inherently unwholesome but are rendered noxious by bad preparation. This is a point which we cannot doubt Mr. Driberg will take means to settle by a series of experiments.

SCOTTISH CEYLON TEA COMPANY, LIMITED.

Capital £50,000, in 5,000 shares of £10 each, of which 4,100 shares, fully paid up, are now being issued.

DIRECTORS.—H. L. Forbes, Esq., Claremont, Waterden Road, Guildford (Chairman and Managing Director.) R. W. Forbes, Esq., 1, Argyll Road, W. John Anderson, Esq., 16, Philpot Lane, E.C.

MANAGER IN CEYLON.—David Kerr, Esq.

BANKERS.—Chartered Mercantile Bank of India, London and China.

SOLICITORS.—Messrs. Murray, Hutchins & Stirling, 11, Birchin Lane, E.C.

AUDITORS.—Messrs. J. B. Laurie & Co., 2 Gresham Buildings, E.C.

SECRETARIES & OFFICES.—Messrs.—Anderson Bros., 16, Philpot Lane, E.C.

As none of the Capital in the Company is now being offered for subscription by the public, no formal Prospectus has been issued, but the Directors think it well that the small body of Shareholders should have some statement from the Board with reference to the position and objects of the Company.

The Company's property consists of

ESTATES.	DISTRICT.	VALUATIONS.
Invery and Waterloo ...	Dickoya	£16,000
Strathdon	"	8,480
Benachie	Lower Dickoya	5,650
Abergeldie	"	5,000
Mincing Lane	Maskeliya	5,370

In all £41,000

These Estates consist of about 1,530 acres, of which about 1,400 are in tea (mostly in bearing) with some fine coffee interspersed, and a large quantity of valuable Cinchona. They are situated at a high elevation, ranging from 3,000 to 5,000 feet above sea level, and will consequently be lasting, and will produce tea of a superior quality. "Invery" and "Mincing Lane," the only Estates so far from which tea has been shipped to the London Market, have already attained a high reputation for the quality of their teas, and in the brokers' lists of averages appear amongst the most favoured of the Ceylon Markets. On Strathdon, Benachie and Abergeldie manufacture of tea will be commenced about 1st September in the large central factory on Strathdon now being erected; hitherto all leaf produced has been sold in its green state. The properties were reported on, and valued by the experienced appraiser, Mr. H. K. Rutherford, whose valuations are well-known to be moderate, and the Company have acquired the estates at the values put upon them by Mr. Rutherford. The Company, while providing in their Memorandum and Articles of Association, for a much wider field for their operations, purpose for the present to confine themselves to developing the estates now acquired, and, taking Mr. Rutherford's figures as a guide, a steady profit of 10 per cent or over may be confidently looked for, when the properties come into full bearing. The Company acquire the Estates as from 1st January, 1889, and the anticipated profits for this year, upwards of £4,000 the Directors purpose to employ, in meeting all preliminary expenses of the Company, and the erection and completion of Factories with suitable Machinery. It is unlikely therefore that any dividend will be paid for 1889, and any balance at credit of Profit and Loss will be carried forward to 1890. The addition to the value of the Estates, by expenditure on Factories and Machinery is very considerable: The only contract entered into is one of 11th July, 1889, between Messrs. H. L. Forbes, R. W. Forbes, Hugh Blacklaw and John Fraser, the Vendors, and Mr. John Anderson on behalf of the Company.

THE REPORTS OF THE UVA AND SPRING VALLEY COFFEE COMPANIES.

The above Reports are always of much interest as affording reliable information on the working of some of the best known and most productive estate properties in Ceylon. It was naturally to be expected that their character on the present occasion would be materially affected by the low rates which have ruled for tea in the home market during the last few months; but we are glad to observe that, in spite of this adverse condition, the current reports which we reprint elsewhere, cannot fail to be on the whole satisfactory to the shareholders of both Companies.

There is one peculiarity which cannot fail to at once strike those who read these Reports. Thus we find the one for Spring Valley stating that the estimate of the coffee crop for the season 1888-89 of 2,000 cwt. will be materially exceeded—by 600 cwt.,—while the report of the Uva Coffee Company informs us that on the group of estates which forms the holding of that Company the estimate of 2,000 cwt. will not be reached by 500

cwt. This is a singular contrast and difficult to account for, for it is to be presumed that the varying conditions of the two properties would have been taken into full consideration when preparing the estimates. While the anticipations for Spring Valley are spoken of favorably, a somewhat lugubrious tone is adopted with regard to the Uva properties. But considering the two reports together, it may be said that on the whole the prospects of coffee are considered to be fairly good, though the directors carefully guard themselves against inducing their shareholders to indulge in too hopeful a view of the future of our old staple. Such a course has certainly been a wise one in view of all possible eventualities; but the general tenor of the Reports will be to confirm the opinions of those who have long thought that coffee was by no means defunct in Ceylon. That in spite of their hesitation in holding out very sanguine expectations to the shareholders, the directors themselves entertain good hopes, is evidenced by their resolution as announced, not further at present to reduce the acreage under coffee. Passing from anticipations for the future to the facts absolutely ascertained with regard to the coffee yield of the past season, we find that on the Spring Valley estates, on which a considerable increase on the estimate for the current year is expected, there was a serious diminution on the estimates prepared for this year, the yield falling short of this by nearly 700 cwt. On the Uva estates, on the contrary, those which are expected to show a heavy fall-off during the season of 88-89, no such proportionate reduction was experienced, in 1887 the reduction on estimate being only about 239 cwt. on an outturn almost equivalent in amount to that of the Spring Valley estates. This comparison reverses any conclusion to be formed from that of the figures estimated for the present season.

We think that on the whole both Companies may be congratulated,—when the adverse circumstances under which their tea has had to be disposed of during the year reviewed by the Reports are taken into account—on the average prices obtained for it. In the case of the Spring Valley Company, we find this stated to have been 1s 1½d per lb., and for the Uva Company 1s 0½d per lb. We note that both Reports indicate a large increase expected in the outturn of tea during the present season. The Uva Company appear to have sold a net production during last year of about 70,000 lb.; while the estimate for the present season is no less than 177,000 lb.; the Spring Valley outturn also for last season being 38,449 lb. and the estimate for that now proceeding being 100,000 lb. We presume that in forming these estimates allowance will have been made for that finer plucking which the Directors announce to be in contemplation, and if so we have in these figures a remarkably strong evidence of the great increase in the export of tea from the Uva province to be looked for. The sale of cinchona bark from the Uva estates realized an average of 5d per lb., while for that from Spring Valley but 4½d was obtained. The directors abstain—and wisely, as we think,—from formulating any opinion as to what the course of this special article of their production may be during the present year. This is an wholly unknown factor at present.

In view of all the circumstances set forth and as known to ourselves locally, we think it will be deemed very satisfactory that the corner of depression has at length been turned, and that the directors of both Companies have been able to recommend moderate dividends. In the case of Spring Valley this will amount for the year to 5 per cent paid free of Income Tax, while in that

of Uva it will be 3 per cent, also free of Income Tax. Recollecting for how long a time the shareholders have had to be content without any dividend at all, we think they may fairly be congratulated on this turn in the tide of their affairs. The figures we have quoted above as to the estimated income in the yield of tea must lead to the anticipation, that, if all goes fairly well with coffee and other subsidiary articles of production, a much more pleasing dividend may be announced when the next annual reports are issued. Those now under comment make reference to the improving condition of the London tea market, a state of things while there is every reason to hope may be progressive. That even with the low prices of late ruling these Companies have attained a comparatively good average of price, warrants the hope of a much better average for the present year, and if that hope be justified, the tremendous increase in outturn must insure quite a brilliant prospect for the directors to report upon when the operations of the present season shall have been closed.

OUVAH COFFEE COMPANY LIMITED.

Capital £100,000 in 10,000 Shares of £10 each.

DIRECTORS.

John Brown, Esq., Managing Director; H. H. Pott Esq.; L. Famin, Esq.; Edward Conder, Esq.

REPORT.

The following Accounts are now presented to Shareholders:—Profit and Loss Account for Crop 1887-88. Balance Sheet made up to 31st May 1889.

CROP, 1887-88.

On reference to last year's Report it will be seen that it was not then thought that the original estimate of 3,300 cwts. of Coffee would be realised; and although this was the case, the shortcoming was not so large as was then expected, the actual weight sold being 3,061 cwts. 3 qrs. 7 lb. The average price of the Coffee sold in London was 85s 4d per cwt., the total proceeds derived from this product being £12,783 9s 3d. The weight of tea sold amounted to 78,771 lb. inclusive of 8,800 lb. bought from neighbouring Estates, and manufactured at the Company's factories, the estimated yield being well exceeded. The tea brought the satisfactory average of 1s 0½d per lb., and a total value of £4,163 3s 3d. The estimated quantity of Cinchona Bark was also harvested, 77,722 lb. being sold at an average of 5d per lb. producing £1,697 13s: a small quantity of Cocoa was also sold for £41 8s 6d, making the total value of the produce secured on the Company's Estates £18,685 14s 0d. The next item on the credit side of the profit and loss account is £1,214 9s 10d under the heading of Machinery account, being the amount spent during season 1887-88 on tea factories and machinery. This work being of a permanent character, and carried out for the treatment of future tea crops, the Board have decided to carry forward the expenditure and to write it off out of the profits of future years. The total expenditure for the year in Ceylon and London, after allowing for profit on Exchange, amounted to £16,767 2s 7d, thus showing a profit of £3,133 1s 3d on the Season's working. To this has to be added the balance of £86 19s 0d brought forward last year, giving at total sum of £3,220 0s 3d. at the credit of Profit and Loss account.

On the 10th January last a dividend of 1½ per cent was paid on the capital of the Company, which absorbed £1,500 of the last named sum, and the Directors now recommend the distribution of a further dividend of 1½ per cent, making 3 per cent for the year free of Income Tax. To meet the dividend now proposed the sum of £1,500 will be required, leaving a balance of £220 0s 3d to be carried forward to next account.

CROP, 1888-89.

The prospects for the above season are by no means so favourable as they at one time appeared. The ori-

ginal estimate of the Coffee Crop was 2,000 cwts., and this off an area of 1,231 acres was by no means a sanguine expectation; it is now certain, however, that the Crop of Coffee will not exceed 1,500 cwts., thus shewing a heavy reduction to be faced. The Coffee tree in Ceylon has for years had to contend with pests which have threatened its very existence, and it is only on specially favourable Estates, where it has been thoroughly well cultivated and cared for, that it has been able to hold out against the combined attacks of leaf disease and green bug. There are thousands of acres in Ceylon where Coffee has altogether ceased to exist, but the Company's Estates are amongst those fortunate ones, where, by good cultivation, the Coffee has still been preserved. Although these pests are now more or less in abeyance, past experience shews that it would be foolhardy to predict what results the Coffee is likely to shew in future years. At the same time the Board feel justified in informing Shareholders that the latest reports state that the Coffee on the Company's properties is looking vigorous and healthy, and as though it would bear a good Crop for the following season.

Coffee is now a very valuable product, and the Board have determined not to replace any more of it with Tea for the present, in the hope that it may recover, and they feel sure that unless Coffee is to become extinct in Ceylon, the Company's Estates are amongst those that will recover.

A further area of 67 acres of Tea has been planted during the past year, and the acreage is now as follows:—

	TEA.						
	5½	4½	3½	2½	1½	6	
	years.	years.	years.	years.	years.	mths.	
Planted							Total
Nov.-Dec...1883...	1884...	1885...	1886...	1887...	1888...		acres
Glen Alpin							
Group ...	9...	145...	272...	26...	16...	57...	525
Narangalla							
Estate ...		82...	93...			1...	176
Hindagalla							
Estate ...		120...	85...			9...	214
Total acreage and present age	9...	347...	450...	26...	16...	67...	915

All the Tea continues to grow very satisfactorily, and the yield of leaf is steadily increasing as the Tea gains age. The estimated Crop for Season 1888-89 is 177,000 lb., and there is every reason to believe that it will be secured. During the past eight months, however, the Tea Market has exhibited great weakness, and extremely low prices have been ruling, the average selling price will consequently be much lower than last year, and the profit on Tea cultivation during the above season will thus be materially less than was expected.

The present demand runs chiefly for fine Teas, and the Company's Estates are now altering their style of plucking to meet the requirements of the trade. This finer plucking will somewhat reduce the yield, but this will be more than made up by the higher price the Tea will realise. The Tea Market has also somewhat improved.

A fair harvest of Cinchona Bark will be secured but the price of this article rules very low. As a considerable quantity of the Tea Crop, and nearly the whole of the Coffee and Bark, has yet to come forward and be sold, it is as yet impossible to say whether Crop 1888-89 is likely to shew a satisfactory result. Mr. Brown has lately returned from visiting the Company's properties, and will state to the Meeting the opinions he then formed with regard to the condition and future prospects of the Estates. A copy of his remarks will also be sent to each Shareholder.

SPRING VALLEY COFFEE COMPANY LIMITED.

Report to be presented to the Twenty-fourth Ordinary General Meeting of the Company on Thursday the 8th day of August 1889, at 12 o'clock noon.

Shareholders are herewith furnished with copies of the following Accounts, viz., profit and loss Account

for crop 1887—88, balance sheet made up to 31st May, 1889.

CROP, 1887-88.

It was pointed out in last report that the coffee crop would fall very short of the original estimate of 3,140 cwt. and it will be seen that the total quantity sold amounted to 2,468 cwt. 0 qr. 10 lb. of the value of £10,679 4s 3d. The coffee sold in London yielded an average price of 87s 1d per cwt.

The tea crop considerably exceeded the estimate of 30,800 lb. Spring Valley producing 38,449 lb which sold at an average of 1s 1½d per lb, and Oolanakande 5,452 lb which obtained an average of 9½d per lb. The total value of tea sold amounted to £2,384 0s 1d.

The weight of Cinchona Bark sold in London was 13,812 lb., at an average price of 4½d per lb. The proceeds from the sale of Cinchona Bark were £269 15s 9d. The total value of all produce sold, inclusive of £13 15s 8d balance of Interest Account, was £13,346 15s 9d, and the year's expenditure in Ceylon and London, after allowing for Profit on Exchange, amounted to £11,355 19s 5d, thus showing a profit on the Season's working of £1,990 16s 4d; to this sum has to be added the balance of £2,595 9s 4d. brought forward from last year, giving a total £4,586 5s 8d, at the credit of Profit and Loss. On the 10th January last a Dividend of 2½ per cent was paid on the Capital of the Company which absorbed £2,000 of the above amount, and the Directors now recommend the payment of a further Dividend of 2½ per cent, making 5 per cent for the year, free of Income Tax. For the payment of this Dividend £2,000 will be required, leaving a balance of £586 5s 8d to be carried forward to next year.

CROP, 1888-89.

The Directors have pleasure in referring to the prospects for this Season. The Coffee Crop was originally estimated at 2,000 cwt., but it is now almost certain that it will turn out about 2,600 cwt, thus showing a very material increase. This is very satisfactory, especially looking to the price now ruling for this staple. The latest advices from Ceylon report that the Coffee is looking well everywhere on Spring Valley, and that with a favourable Season, it bids fair to give a satisfactory Crop again in the following year. In the meantime, there is a comparative freedom from green bug and leaf-disease, but it is impossible to say how long these pests may hold off. The area now under Coffee is 970 acres.

The Tea Crop was estimated at 100,000 lb. on Spring Valley, and this total will be very nearly, if not quite, reached. Fine Tea being now in demand in London, finer plucking than formerly has had to be resorted to, and although the quantity of Tea to come forward will be thereby decreased, the result will be a considerable improvement in price. The Tea market has ruled exceptionally low during the greater part of the Season, but the tone at the time of writing is decidedly firmer, so that the prices to be secured for the remainder of the year's Crop should show a distinct improvement. The average price for the Season will, however, be considerably lower than that obtained in 1887-88.

The Tea area has been increased by 20 acres during the past Season, and the acreage now stands as follows:—

Planted	Acres
Nov.-Dec., 1884, on Spring Valley 271, now 4½ years old	
May, 1885, on Oolanakande 143, now 4 "	
Nov.-Dec., 1885, on Spring Valley 230, now 3½ "	
May, 1886, on Oolanakande 7, now 3 "	
Nov.-Dec., 1888, on Spring Valley 20, now 6 months old	

Total area under Tea 671 acres

All the Tea is growing and yielding leaf well, but considering the present condition of the Coffee, and the high price ruling for that article, the Directors have decided not to replace any more Coffee with Tea for the present.

PROSPECTS OF THE CEYLON TEA ENTERPRISE.

The mail has brought us a very re-assuring letter from Mr. Roberts of Messrs. S. Rucker & Co. Our correspondent emphasises the position he has always taken, that the demand for our teas, their superior character being beyond doubt, is likely to increase instead of diminishing as the crops increase, dealers being encouraged to buy largely because of the moral certainty that they can continue to supply their customers regularly with an article of the same quality. The quantities of Ceylon tea taken for consumption in seven months of this year and especially in July, when the deliveries considerably exceeded the imports, are adduced in support of the argument, and although recent low prices stimulated the demand which has led to such results, yet in view of the present and especially the prospective results, the low prices are regarded as a benefit rather than the reverse. This is a proposition which, of course the individuals who have specially suffered from low prices will find it most difficult to concede. Looking at the enterprise as a whole the statistical position is certainly eminently favourable. The absolute increase in deliveries of Ceylon teas in the seven months, is in excess of the figures for increase in Indian, while stocks of Ceylon have been reduced to about two months' supply, should the July rates continue. The figures for the seven months are the more satisfactory as showing that Indian and Ceylon teas have not merely replaced China kinds, but that there has been a considerable increase in total deliveries, notwithstanding the fact recognized by Mr. Goschen in his budget speech, that one pound of Indian or Ceylon tea is equal to nearly two of China. This important fact we are apt to lose sight of in looking at the bare figures. These for the first seven months of this year shewed that, by a process which is now steady and continuous, the deliveries of China teas, which once had the monopoly of the market, shewed a decrease on the corresponding period in 1888 of 11,502,000 lb. Indian and Ceylon on the contrary showed increases represented thus:—

Indian	7,458,000 lb.
Ceylon	7,763,000 "
Total	15,221,000 lb.

The absolute increase in deliveries, therefore after deducting the decrease in China was 3,719,000 lb., which, certainly represents 6,000,000 of the China standard of quality. If the process goes on at the same rate to the end of the year, and after the same fashion, we may anticipate an absolute increase of deliveries over 1888 of about 7,000,000 lb. which being all Indian and Ceylon will be equivalent to about 12,000,000 of China quality.

The excess of increase of deliveries of Ceylon teas over Indian shews thus:—

Increase of Ceylon teas delivered	..	7,763,000 lb.
Do. Indian	..	7,458,000 "

Excess in favour of Ceylon .. 305,000 lb.
The excess is not large in figures, but the case or different when we look at percentages:—

China lost 11,502,000 on 64,352,000 or 17.87 per cent.
India gained 7,458,000 on 48,751,000 or 15.29 per cent.
Ceylon gained 7,763,000 on 9,579,000 or no less than 81.04 per cent.

Statistically, therefore, the Ceylon tea enterprise occupies a very high position. Let us trust that the profits to individual growers of our new staple product may be in proportion.

THE PROSPECTS OF TOBACCO IN CEYLON.

The accounts we get are of rather a mixed description: for instance, we learn that an attempt to cultivate tobacco on a 50-acre young tea clearing of Mariawatte near Gampola, has been a comparative failure. We suspect that neither the climate nor soil is suitable. On the other hand the past or present season has been a most favourable one for the tobacco drier Matale and Kurunegala districts. From the latter especially, we learn that Mr. Ingleton's Syndicate patrons are delighted with their Deigoila fields of tobacco this year and expect a handsome return. Nevertheless, it is very evident that tobacco can never to any great extent be a European planting industry in Ceylon. Save at a few points, tobacco culture here should be a pursuit for natives each cultivating a small garden and doing full justice to an acre or half-an-acre and selling the crop. And in this connection it is of interest to know that the practical tobacco curer sent out by Mr. T. Dickson's Tobacco Company has arrived in Colombo, and is at once to go to work. From an interview reported by a contemporary with him, Mr. Boyd, we quote as follows:—

The Cigar Manufacturing Company some time ago, made Messrs. Cumberbatch and Company their Colombo Agents, and entered into an arrangement with them by which Messrs. Cumberbatch & Co. consented to give up a portion of their (Ambewatta) Mills to allow the Company to carry out its operations. This done, the Company despatched a gentleman well acquainted with the art of cigar-making, and he arrived here in the "Paramatta" on the 20th instant, in the person of Mr. J. T. Boyd, who, although a young man, is well acquainted with the work and likely to make the affair a success. Mr. Boyd says that at present all they are doing is getting the mills ready, a work which ought not to take a long time, as not much is required. To make cigars, he pointed out, it was necessary to soak the leaves in water in a zinc sink, and then take them out and leave them for a day, by which time they are in a damp condition suitable for cigar making. Then the inside part of the cigar, technically called the "fillings," is rolled up, after which the second parts, known as the "bunch wrappers," are added, and then they are passed through moulds which render them of the proper shape, after which the outside leaf which is generally a finer leaf, is added, and then the cigars are placed in a drying room and brought into condition. It will thus be seen that whatever machinery is required is very simple, while the structural alterations necessary at the mills to secure an air-tight compartment will not be extensive. The work of preparing the mills for the purpose, however, is just about to be commenced, and working will be begun shortly. The Managing Director is Mr. Thomas Dickson of Fenchurch Street, London, while other Directors are Mr. Brown and Mr. Shaw. There are two other Directors, too, whose names he does not know. The Secretary is Mr. E. G. Reeves, who Mr. Boyd says he believes is a relative of Mr. Gordon Reeves, of Hoolland Estate. The London offices of the Company are in Tokenhouse Buildings. The Company intends manufacturing on a large scale eventually, he says, but they propose to start with a staff of about 20 men, and then engage women to help in the work. On this point, however, Mr. Boyd has met with his first difficulty, for most of those here who know anything about cigar making, he says, are employed by the petty manufacturers here, and he has a job to secure workmen. Our reporter accordingly asked if it would be possible for the raw native to be taken and instructed in the art, and Mr. Boyd said that was what he should have to do if he could not get the labor he sought; but he added that this would not be satisfactory, for it would take a long time to teach them to make cigars properly. Questioned as to his own experience, he said that he had never manufactured out of England, but that his

father, Mr. J. F. Boyd, had been a cigar-manufacturer in Leicester, (in fact he had one of the large places there of any of the 25 cigar-makers which Leicester boasts of) and that he had worked under him and been through every branch of the business. With regard to the tobacco to be used, Mr. Boyd said that it was intended to buy Ceylon tobacco partly for the purpose, and also tobacco grown in Sumatra. He believed that one of the Directors was a Sumatra tobacco-grower, though he did not know his name. He would buy what Ceylon tobacco was required. It was not intended to have agencies throughout the Colony. With regard to the sale of the cigars which the Company prepared, Mr. Boyd said that they expected to find a market for them both here and at home. The West Indian smoke, he knew, was popular at home, but with properly-cured tobacco the East Indian cigar in his belief would compare very favourably with its West Indian rival. All he wanted was to get the labor, and then, with the mills ready, he said a start could soon be made. We hope that he will be successful, and that the new enterprise will prove a paying concern.

Since the above was written we have seen the following reference to the Mariawatte experiment. Writes an upcountry correspondent to a contemporary:—

I do not think that the area over which tobacco can be successfully grown upcountry is very large, that is, if the experiment made at Mariawatte is any criterion. It has been carried out most carefully under Mr. Jamieson's supervision, and under the guidance of Mr. Vollar, but the plants are uneven in growth, and show little of that luxuriance which one expects in tobacco.

PROSPECTS OF COTTON CULTIVATION.

In contrast with the report of a tobacco failure, it is stated that the clearing of cotton (among tea) on Mariawatte is doing very well and promises to be as good a success as was Mr. Blackett's on Jack-tree Hill. In the North Matale district we learn that Mr. Borron is clearing some 130 acres for cotton on behalf of the Cotton Spinning and Weaving Company, and we trust this, we suppose the biggest, cotton plantation yet systematically attempted in the island, will be a success.

TEA CULTURE AND PREPARATION.

ANSWERS TO QUESTIONS.

(Continued from page 176.)

VII.

Agrapatana District: Elevation 4,600 to 5,900 ft.

1. *Pruning*.—At this elevation I find that pruning early in the year, say March to May, gives the best results. I have tried pruning in June and July and August, and it was 5 months before I got any returns. This year, tea I pruned in February, March and April, I was plucking in May and June. In future I intend to prune all the year round avoiding the months of December, January, June and July. As to "how to prune," I have no "hard and fast" rule: it all depends on jät, elevation and aspect.

2. *Plucking*.—After pruning, I leave 4 leaves above the first leaf, then 2 or 1 leaf (depends on jät) secondary growth, and one leaf or $\frac{1}{2}$ leaf tertiary growth, and so on to end of season. As a rule I pluck round every 8 days, taking the bud and 2 leaves and the $\frac{1}{2}$ leaf, and when I see that the bushes require it I drop the $\frac{1}{2}$ leaf plucking, only taking the bud and 2 leaves. Taking the $\frac{1}{2}$ leaf gives a large per centage of pekoe souchong, but as long as my average remains over the 1s I think it pays.

3. *Withering*.—I, as a rule, wither down to 65 per cent.

4. *Firing*.—I think tea should be fired as nearly crisp as possible without being "too much" so. I have never sifted while firing, it is not necessary with a Victoria drier which I use. L

VIII.

Ambagamuwa: Elevation about 3,500 feet.

There is not much new light that can be thrown on the above. Practical men of various districts, climates and elevations have already contributed to our general knowledge much, if not all that they could say, of what they tried and found best suited to their own special estates, and what general knowledge we have will always have to be modified to suit each estate and even the different fields of each estate; e.g. one would not pluck a flat and a hill alike after pruning: nor a forest clearing and a chena clearing. If one waited for shoots with eight leaves in the impoverished soil of a patch formerly in coffee, he might lose his opportunities and perhaps half the season. So also with other details in the field. So that many of our pet dicta will ever remain open to modification, and one should be slow to generalize or hazard opinions.

1. As regards *pruning*, since the continuous rains and the strong winds of July minimize the yield and interfere with labour in most places, apart from the contribution towards costly and unsatisfactory manufacture, this should be our month for pruning on grounds of prudence and economy, if other conditions were not unfavorable.

2. *Plucking*.—I found it always best to let the bush establish itself somewhat: the new stems mature, the lower leaves develop to full size and change from light to darker green and then I nipped off the convolute bud and the lower leaf. I repeat this for a few rounds, till the secondaries are ready to pluck. Gradually I get into the usual mode of plucking. When by patience at the start the bush is allowed to form, then hard plucking may afterwards be practised with impunity, and the leaf will be found to yield better results in the cup. Should, however, the impatient proprietor fall tooth and nail on the tender and immature bush just forming, and carry away basket after basket of the succulent flush, he may be rewarded with similar flush for a few rounds, after which he will find the yield fall off rapidly, leaving him a stunted bush to work upon for the rest of the year. Nor will the tea manufactured from such succulent vegetation do more towards the good name, fame and reputation of Ceylon than compete with the four-penny Chinas in the Lane.

3. *Withering*.—The average for good tea has been found with me to be 66 lb. out of 100.

4. *Firing*.—It will matter little if there was any neglect in the firing, if after sifting, the tea is re-fired the next day and placed in the bins hot. The temperature of the drier should not be higher than is compatible with the work of the factory. It is better to incline to 200 than 300 when possible.

IX.

Pussellawa: Elevation, under 4,000 feet.

In replying, as requested, to the questions regarding tea culture and preparation, I think no hard and fast rule of action should be adhered to, as regards pruning or plucking. Much depends on the seasons, as well as on elevation, climate, &c., and the condition or state of the bush, must determine one's course of action.

1. When is it best to prune? Opinions differ as to when it is advisable first to apply the knife to the tea-bush. Many think it should be left to run, untouched for three years. For my part I think "topping" (*i.e.* merely cutting across) advisable, when a tea-bush is from 18 months to 2 years old. The knife should next be applied when the bush ceases to flush readily: this generally happens from 12 to 18 months time from the last pruning. How should pruning be done? Exposure, elevation, the jät of the tea bush, the time of year, are all factors which must be taken into consideration in determining what method of pruning should be adopted. Everyone is agreed that a low jät bush should be cut down very low while a high jät bush can be topped with advantage at a height of 18 inches. When pruning is again necessary, the state of the bush, and growth of the new wood, have everything to do with arriving at a decision whether to cut the bush down again to the level of (or even below) the original cut, or to prune two or three inches above

it. If the latter course can be adopted, the bush will, in all probability, admit of each successive pruning being done with advantage 2 or 3 inches above the last cut, until the time arrives for cutting down again to a low level. Leaves adhering to the main stems should be left on the bush, and this is the more necessary if pruning in the dry season.

2. *Plucking*.—After pruning, the primary shoots should be left to throw out 8 to 9 leaves, when they should be plucked back, leaving 3 to 4 full leaves on the bush (when the bush is young, it would be well to leave 4 leaves). When the secondary shoots come out, 1½ leaf might be left, including the first leaf if a well-grown leaf, but excluding it otherwise. When the tertiary and other shoots come up, 1½ leaf should be left on the bush, and the rest of the flush taken. This applies to ordinary medium plucking. By leaving one full leaf (instead of a leaf and a-half) one gets a finer plucking, but I do not think the bush flushes as readily as when a leaf-and-a-half is left. This method of plucking can be continued till the end of the season, altered occasionally according to the state of the bush; for instance, if the bush flush freely, and there is plenty of green bearing wood upon it, only a half leaf can be left with impunity, otherwise a leaf, or a leaf-and-a-half, should be left.

3. Green leaf should lose about 40 per cent (*i.e.* 100 lb. green leaf should wither down to 60) to secure a good wither.

4. I think tea should be fired till it is crisp but not highly-fired. For those who have facilities for sifting, it may be well to sift when firing; but as the leaf is sifted in the roll (prior to the coarse leaf being returned to the roller to be re-rolled) I think this unnecessary.

F. C. G.

X.

Around Kandy: Elevation Under 2,000 Feet.

1. *Pruning*.—In selecting your best time for pruning the one great object in view should be to get your trees into the best flushing order during the fine months of the season, when you get your heavy pluckings and also make your best tea. July, August, September, I consider to be the best months for pruning; for then, after heavy pruning you will be able to make a fresh start in plucking, say in October and November. As the first few rounds will give you little chance of either getting a good plucking or turning out good tea, you will fairly be established in good pluckings only from the beginning of November, and your trees will then be in the best possible condition, say, till the end of May. As to how pruning should be done, is a matter of great importance, as you will very often find that good pruning and careful pluckings are the great factors in your attaining the estimated crop rather than anything else,—do your pruning thoroughly well. When I say thoroughly well, I do not mean a further outlay on the estimated pruning expenditure; but very careful work. Cut your bushes down to a level on a given height, care being taken so as not to have the centre of the bush higher than the sides, but quite flat, if not slightly inclined towards the centre. Having done this you begin to clear the centre of the bush of all brushwood formed through continual pluckings, and all useless twigs; but if you are working 2 or 3 inches upon your previous year's pruning, you will not find much of the former at your pruning-level if your pluckings were properly conducted. Any old useless wood not capable of forcing out strong healthy shoots should be cut clean off, retaining as much of the newly-formed wood as possible. All knotty heads of branches should be cut off; as otherwise, instead of forcing good strong shoots, they will only throw out a number of thin wiry shoots, however strong the wood may be. Coolies, unless strictly looked after in pruning, are apt to do either too much or too little. They will either cut off much of the healthy wood, or leave a good deal of what should be pruned off, resulting in either case in a reduced yield. The former will only reduce your yield, while the latter will also affect the quality of your tea.

2. *Plucking* should be done when the shoots after pruning have grown from 6 to 8 inches high. For the first two rounds pluck only the bud and the lower leaf attached, leaving 4 to 6 leaves on the tree. Care should be taken to nip off any "banjy" at your level as you go along. Until the third plucking you will have only the primaries ready for plucking, after that the secondaries will also be ready to be plucked, and then you begin to pluck all that you can with one operation of the hand pluck $2\frac{1}{2}$ leaves, leaving $2\frac{1}{2}$ leaves on the tree. For about 3 or 4 rounds you continue plucking as above; and then you do it a little closer, leaving only $1\frac{1}{2}$ fully-formed leaf, and so continue closer and closer, the harder the trees grow, until towards the end of the season you leave only a half-leaf on the shoot.

3. To obtain a "good wither" from 30 to 35 per cent of the wet leaf must be lost. The leaf plucked on a hot sunny day will not lose over 25 to 30 per cent on wet leaf; but on a cold and moist day, although the leaf is not actually wet, it will be found fully 40 per cent less on attaining a good wither.

4. Tea should be *fired* till quite crisp. This can be best told by the touch of an experienced hand. Sifting when half-finished is necessary in chula firing, but it is not necessary in a sirocco firing for these reasons. (1) The meshes of the sirocco drying-trays being larger than the chula trays, allow the broken tea and dust to fall through in stirring and escape burning. (2) The continual stirring of the leaf in the trays helps the intense draught in the sirocco drying chamber to dry the tea off in a less time than the chula, avoiding the risk of burning, and drying the contents of the tray equally.

COCHIN TEA MAKER.

XI.

Lebanon Group, Madulkele:

Elevation between 2,800 and 4,800 feet.

In reply to your request for answers to the questions re tea culture asked by B., I have pleasure in giving them below. My elevation is from 2,800 feet to 4,800 feet. Rainfall about 120 inches well distributed. Acreage of tea worked by me nearly 1,000.

1. "When is it best to prune and how?"—This is a large order, and I really feel I am only learning the best seasons and methods of pruning. For this district July pruning is undoubtedly the best. Trees pruned in this month make splendid wood and escape the strong June-July S.-W. winds. There is little flush also about this time and therefore little lost by pruning. My heights for pruning a fair to a good jât are as follows:—Top at 12 months to 12 inches and at 24 months cut down to 16 inches. The third year I would prune to 18 and the fourth to 20 inches and would commence again at 16 inches in the fifth season. I have yet to learn a lot about this work, and wish I now had the experience and knowledge I hope to possess 5 years hence.

2. "How should tea be plucked after pruning till end of season?"—The lower you prune the longer you must let the ensuing flush grow. As a rule I leave, for first flush two-and-a-half leaves, for second flush one-and-a-half, and then half-a-leaf only for the rest of the season. Two months before pruning a little judicious stripping often brings in a lot of leaf resulting in no harm to the bushes. I am most careful to leave all side branches to grow of their own sweet will. When your tea is 8 to 10 years old or perhaps 6 to 8 on young land, you can pluck all round your bush, for then your bushes will cover the ground and can stand hard plucking.

3. "About what percentage should be lost in withering?"—I wither as hard as I can without actually drying the leaf. This means losing 40 per cent of moisture, or in other words withering down to 60 per cent.

4. "Should tea be fired till quite crisp &c.?" I do not like firing till quite crisp, but always put away in big baskets when just *not* crisply fired. Teas put away in this condition will be found quite crisp and thoroughly dried next morning, and by so doing all

risk of burning your teas is avoided. I use Jackson's Victoria and Venetian Driers and therefore find no necessity for sifting half-fired roll. The roll is always sifted before firing, and, of course, the small is fired separately from the big. T. D.

XII.

Kotagala: Elevation over 4,000 feet.

1. From the latter part of July to the earlier part of September I have found to be the *best* time to prune; my experience has been gained at an elevation of from four to five thousand feet and from three to six hundred feet.

In order to make the bush spread and prevent it running up whip-like, it ought to be cut across at 10 inches to 1 foot the first year. When there is any wind this ought to be done at the commencement of the S.-W. monsoon and repeated at 15 inches at the same time the following year. After that with fair jât it is I think to the advantage of the bush to let it run for two years before cutting again, and then cut according to the bush. I have tea flushing fairly well on poor land at 4,500 feet elevation that was cut across in April 1887 and has not been touched with a knife since. Up to the very cold wet weather it never showed the least sign of wanting pruning.

2. My style of plucking is very much on the lines laid down by Mr. Armstrong in his special paper on Tea Cultivation, published at the *Observer* Office, viz. after pruning with good to fair jât pluck primaries leaving three whole leaves and the "fish" or mother leaf, leave two whole leaves on the secondaries and one on the tertiaries. After that leave one whole leaf and the fish leaf up to say within a couple of months of pruning and then take as much as possible, *but on no account must the "mother" leaf be taken* or the shoot will die back. Whenever possible the prunings from all trees over three years old should be buried. They make a valuable manure which is there on the spot transport free, and merely for the application.

3. The average loss in withering is about 35 per cent.

4. I think the three-quarter system of firing preferable. If tea is fully fired at first a large per cent of the flavour goes off in final firing, whereas in the other case it is preserved. Teas fully fired at first and put in a bin for a few days have a heavy sourish smell which is not present when the tea has been three-quarters fired and the moisture allowed to evaporate a little before finishing the firing. It is not necessary or advisable to sift tea while firing with a "drier" as the act of turning the leaf on the tray takes out the smaller leaves as they get dried, and more sifting would tend towards the twist.

My experience of tea on old land is too limited to enable me to answer the questions of "W." fully.

W. H. M.

XIII.

1. When is it best to prune and how?—It depends on elevation.

2. How should tea be plucked from the first picking after pruning till the end of the season?—Leaving six inches above, after that one and a half leaf.

3. About what percentage should be lost in withering to get what is called a "good wither?"—35 per cent.

4. Should tea be fired till quite crisp or not, and should the teas be sifted while firing, so as to get all leaf equally fired?—Should be fired till it is crisp and with chulas should be sifted; not with machines.

G. A. T.

XIV.

"When is it best to prune, and how?"—In temperate climates, nature decides the time. When deciduous trees and shrubs drop their leaves, and plants of all sorts go to rest on the approach of winter, everyone knows that then is the time to prune. Here in Ceylon where we have no winter we must be guided by conditions.

In many districts, and at high elevations,—3,000 feet and over,—there is generally a cold wet season sets in after June. The soil gets saturated and cold. The tea bushes almost refuse to flush, the little they grow is small and bany. They want rest. Then is the time to prune: pruning will assist them to rest. Being deprived of their freshest wood and bulk of their leaves by the operation, they will scarcely show a live bud for weeks. The bushes will thus have their needed, though short rest during the deadeast part of the year, and will be getting ready and in flushing order again for the best months.

In the lowcountry, conditions are different, especially in those parts where long droughts prevail during the first quarter of the year. In such cases pruning should be done so late as only to reserve time for the bushes to regain sufficient young wood to enable them to endure the severe spring drought. By early pruning—about June and July—the young woods gets so well matured, and ripened, the severe drought in the early part of the year drives them all to seeding—and what should be the best flushing months are lost. These remarks, however, both as regards high and low elevation, only apply in a general way: each one must be guided by conditions and circumstances peculiar to his situation, estate, climate, and jât of tea. The latter especially: for instance, in not a few of the estates in the lowcountry there is a great deal of wretchedly bad jât. The planter is almost driven to his wits, end to know how to act with it. The dwarfish creeping stuff leaves him no choice but prune it severely, after which—as everyone knows—the tea made from such is of the poorest quality for months; and anon discovers to his disgust that he has little more than got into fairly good leaf again when his bushes have begun to make blossom buds—which means that the strength and flavour of his teas decrease at the same rate as the blossoms increase. Under such circumstances I can offer him no advice. It will not pay to pick off the blossoms—so I prefer to leave him to his own meditations and pass on to try to answer the other part of the question.

“AND How?”—To make pruning easier and tea bushes in every way more satisfactory. They should be carefully formed from the beginning. Young plants should never be allowed to run up (as is often the case) one or two stems to a height of four or five feet, before topping. They should be gone over with the knife when about eight or ten months planted and all running up stems cut down to eight or nine inches, and thus force them to throw out, and grow, a cluster of shoots, of as nearly equal strength as can be got to make a well-formed bush.

Bushes thus equally formed, and good jât, “How to prune” may be stated in few words. Cut three inches above the last year’s cut. Clear out all wiry and seed-bearing twigs, also cross branches, but spare every leaf you can. Coffee leaf-disease taught us the value of leaves. It should not be forgotten, however that pruning—though indispensable—is a waste of material, and the experienced planter will see that he can occasionally stave off a regular pruning of some of his fields for probably a whole year by merely cutting off the matted surface and levelling the tops of his bushes, but this can only be done where there is good jât: with the low trailing stuff, of all distorted habits, he hardly knows how to act other than to denounce the man who sold him the seed and sold him at the same time.

“How should tea be PLUCKED from the first picking, after pruning till the end of the season?” If the jât is good, the bushes vigorous, plucking may

begin when the young shoots have reached to seven or eight inches. In successive pluckings one leaf above the abortive leaf should be left for say a third of the season. After which the abortive leaf only may be left, but the strength and quality of the bushes must be taken into account in every case, close plucking forces the bush to push at too many points, the flush in consequence is smaller. A larger proportion of fine teas would be made, but a greatly reduced outturn would be the result; besides the bush would get close and matted at an earlier part of the season and necessitate earlier pruning.

In the case of bushes not vigorous the young wood should not be touched after pruning till it has reached to nine or ten inches. A plucking might then be taken off and the shoots pinched down to a level surface leaving about five inches: this will cause fewer and stronger shoots. The advantage is obvious.

W. M.

TEA PLANTED ON OLD COFFEE LAND.

ANSWERS TO QUESTIONS.

No. E.

1st. What do you consider the average age of the tea from which first pluckings have been taken?

Answer:—2½ years.

2nd. What do you consider the average increase during the second year’s plucking over that of the first year’s?

Answer:—200 per cent.

3rd. What is the average increase of the 3rd year’s plucking over that of the 2nd year’s yield?

Answer:—33 per cent.

4th. What is the average increase of the 4th year’s plucking over that of the 3rd year’s yield?

Answer:—10 per cent.

5th. What is the average increase of the 5th year’s plucking over that of the 4th year’s yield.

6th. At what age do you consider tea in such lands in full bearing?

Answer:—5 years.

G. A. T.

No. F.

1st.—About six months later than if planted in new land, say two and half years.

2nd.—The increase of the second over the first year will vary from 40 lb made tea to 120 lb.

3rd.—The increase of the third year over the second from 60 to 150 lb.

4th.—From 40 lb to 150 lb.

5th.—From 30 to 150 lb.

6th.—About the 9th year at a low altitude; 11th at a high.

The question of whether tea on old coffee land can be grown to pay depends much upon the coffee land. For instance it may have been worked out in coffee, mamoty-weeded and been undrained. My experience goes against most land which has been much worked in coffee, no matter how good the soil originally was. Those estates which were cultivated the highest in coffee do not certainly always do the best in tea. Well drained and weeded coffee estates from the first which have not been highly manured, appear to do best in tea. That portion of the estate cultivated the most in coffee usually seems the barest in tea. Of course exposure, wind and other questions come in; where much lime has been used tea seeds well but does not grow large or flush satisfactorily. It also depends upon the degree of goodness in soils. I was recently passing through some land where coffee had been grown for forty years and the tea was yielding 700 lb. an acre, but this is not the ordinary state of things and other fields fell off, the ridges doing little or nothing. It is always difficult to lay down a rule for tea-land; indeed to find any general law for agricultural.

No. G.

Yield of 220 acres Tea, ALL on old Coffee Land, opened in 1858.

From	Made Tea:	Yield per acre:
	lb.	lb.
1886-87....	17,700	about 80
1887-88....	38,500	" 176
1888-89....	94,000	" 429
1889-90....	95,000	estimate 431

The above estate, when in coffee, yielded 13 cwt per acre for many years. T. D.

CEYLON TEA AND ITS PROSPECTS:

ENCOURAGING PROSPECTS OF CEYLON TEA, ABLY ARGUED BY MR. J. H. ROBERTS, OF S. RUCKER & CO. INCREASED CONSUMPTION OF CEYLON TEA IN 7 MONTHS OF 1889, EXCEEDING THE INCREASE IN INDIAN.

9th August 1889.

DEAR SIR,—Having watched the movements of the Produce Markets in Mincing Lane, during the long time I have been connected with them, induces me to offer a few remarks respecting CEYLON TEA, which, if not encroaching too much on the valuable space in your paper, I think may tend somewhat to dispel the gloomy views indulged in by many Ceylon Tea growers (as evinced by the pessimistic letters lately published in your columns)—and who seem to have alarmed themselves very unnecessarily as to the general future course of the market. I ventured a short time ago, on two or three occasions, to express my views, that, far from any permanent depreciation in the value of Ceylon tea owing to the increased supply, we were more likely to have a steady improvement in prices, and I am happy to say my opinion has recently been borne out by facts. It appears to me that a much broader view should be taken of the future prospects of the article, which, it must be remembered, is comparatively a new one, than to draw conclusions of such a desponding nature as have been expressed, based upon the results of only one or two months' prices instead of taking a wider range spread over a longer period. The effects produced from the limited results I have alluded to might become of a damaging character to the future welfare of this promising enterprise and the credit of the island.

I endeavoured to point out that while the supplies from Ceylon were relatively small, dealers here had not sufficient encouragement to push the sale, from their inability to continue meeting the demand which followed the introduction of the article amongst the retail trade, but as soon as the quantity became larger, there would be a much greater incentive to stimulate the demand which would lead to increased competition and enhanced prices.

I further remarked that where Ceylon tea was used, it was much preferred to China, and in many instances to Indian, and when once you could command a wider channel for distribution, consumers throughout this country would so appreciate Ceylon tea, that they would not return to any other, even at some difference in price. Therefore to promote a more general use, it stands to reason we must have a larger supply, nor do I consider there is the least cause for alarm if the production of Ceylon eventually reached 80 or 100 million lb., confident that even this country could take the entire quantity, though of course it would be to the displacement of a corresponding proportion of China, and probably some Indian.

The lower prices ruling a short time ago, which so much alarmed some planters, though only of temporary duration, as evidenced by the marked improvement recently experienced, were really more advantageous to the distribution of the article; and my experience tells me, that the apparent evil will have caused a permanent and lasting demand not obtainable by the most extravagant advertisements. That Ceylon tea is daily becoming more liked throughout this country is palpably evident from the increased deliveries, which last month were 3,677,728 lb., thus exceeding the imports by 800,000 lb.; and taking the total deliveries from 1st January to 31st July 17,342,716 lb, against 9,579,408 lb. for the first seven months of last year. The stock of Ceylon tea was reduced on the 1st instant to 7,381,266 lb., being just two months' requirements if at the same rate as those for July.

These are encouraging facts for Ceylon tea growers, and strongly support the expectation that the increased production of the island can be entirely absorbed in this country.

I subjoin the following tabular statement which shows the deliveries in each month of this year as compared with last year, of China, Indian, and Ceylon teas, by which it will be seen that while the deliveries of China tea have decreased this year 11,502,000 lb., Indian has increased 7,458,000 lb. and that Ceylon has exceeded Indian in an increase of 7,763,308 lb.

—I am, dear sir, yours faithfully,

J. HENRY ROBERTS,
S. Rucker & Co., Tea & Colonial Produce Brokers,
12, Great Tower Street, London, E.C.

CEYLON TEA IN AMERICA.

(From the American Grocer.)

Those interested in the Ceylon-American Tea Company are again agitating the subject of launching Ceylon tea in the market or among the dealers in America, and the aid and support of the merchants in Colombo have been enlisted for the purpose of pushing the scheme. The *Tropical Agriculturist* reports that complaints are already made because a representative of the company who is to be the general manager in this country, has not already started

for New York. As we remarked several weeks ago, when the prospectus of the company was published, our Ceylon friends must realize at the start that the demand throughout this country is for Japan tea and that this preference will not be easily overcome.

[But surely our friends of the *Grocer* will aid in getting a fair field and no favour for a good pure product like Ceylon tea: the new Company has no intention to interfere with existing tea dealers but rather hopes to work through them.—Ed.]

A RIVAL TO HAVANNAH.

THE VIRTUES OF VERA CRUZ CIGARS.

The State of Vera Cruz raises about 5,000 tons of tobacco per annum, and exports about 700 tons. England is the greatest buyer, taking £96,000 worth of manufacture and £5,000 worth of raw, or £101,000 out of a total of £140,000. This export is believed to be only a preliminary to a very extensive foreign trade. The climate and soil are very suitable to the tobacco plant, and there is a wide field for the employment of British capital in tobacco planting, especially if the capitalist allied himself with the local cigar manufacturers, who are always ready to buy or make up leaves of equal size, colour, and quality, conditions which can only be obtained by a regular system of planting, sowing, curing, and sorting. Buying raw tobacco in the open market is a lottery, and leads to the present unevenness in the colour and flavour of the Vera Cruz cigar, which is found in so many otherwise good brands. Planters often operate with very little capital, and have to mortgage or sell their crop while it is growing, conceding to the mortgagee or buyer, as the case may be, large interest or profits to cover the risk of crop being lost. But planters with command of sufficient capital make very large profits, especially those who combine cigar-making with planting. As regards price there is always a large margin between the lowest and highest. Some tobaccos can be bought for 7d per lb. of small planters, while the highest qualities fetch even on the plantation as much as 5s per lb. The prices of the cigars range from £3 9s per 1,000, weighing 8 lb. per 1,000, to £17 10s per 1,000, weighing about 20 lb. per 1,000. The cigar which is principally exported for England is the "condh fina," weighing from 13 lb. to 14 lb. per 1,000, the local price of which is £3 9s per 1,000. The making of this cigar costs about 50 per cent of its wholesale price. The workmen are paid by the piece, the prices ranging from 2s 9d to 13s 4d per 100. A good workman can make 200 cigars of medium quality in a day, receiving 10s 6d for his day's work; but a first-class maker will often earn at finest work 18s a day. The price of a cigar often depends more on the quality of the make than of the tobacco, skilled labour being dear, especially in the towns where living is very expensive. The principal cigar manufactories are in the town of Vera Cruz, where one maker alone exports £50,000 worth of cigars per annum to England.—*P. M. Budget*, Aug. 8th.

TRIP TO THE TRAVANCORE DISTRICT.

On my return to Cochin I found that the Resident had come back, and we paid him a visit on his island opposite the town. The Resident of Cochin and Travancore has his lines cast in very pleasant places. Some five or six palaces are kept up for him all along the coast from Cape Comorin to Cochin, and he has besides a house on the Permade hills and another at Courtallum, the

sanitarium of Tinnevely. Numerous boats are kept up for him for travelling and while the position is dignified he has but little to do, for the States to which he is appointed are so-called model ones, and there are none, or at all events few, of the ructions which occur in States like Hyderabad, Bhopal of Indore. He can get as much big-game shooting as he likes, and lives in a fair climate where it is never very hot and never very cold.

From Cochin to Trevandrum, the capital of Travancore, is a distance of 120 miles. The journey is done by cabin boat with ten rowers as before: and such is the endurance of these men that they can go the whole distance without a break. We pass Alleppey, an important seaport about 30 miles from Cochin, at night, and early next morning are near Quilon, another port of importance. We have been travelling all the time over backwaters, sometimes broad like a lake, but, generally speaking, about the size of a good-size river. Everywhere are dense masses of coconut trees, from which indeed the chief portion of the revenue is derived. A tax is levied on each tree instead of on the land, and as it is very small the growers make large profits. A coconut tree should yield an annual profit of one rupee, and as they are planted very thick a man owning ten acres of trees is a rich person. There is perhaps no tree in the world like the coconut tree of which every part can be utilised. The timber, the leaves, the web-like covering that binds the leaves to the trunk, the spathe, the nut, the sap or juice, even the very roots, which when the ground is dry penetrate an enormous distance in search of water, are useful as articles of commerce; and not only can each part be utilised, but it can be used for so many different purposes. The juice of the tree is made into toddy, arrack and into jaggery, or a coarse kind of sugar; the outside covering of the nut or husk is made into coir; the inside shell is used in a number of different ways, from a spoon or ladle down to firewood; the water of the nut forms a refreshing drink; from the flesh is extracted coconut milk, and when allowed to ripen is pressed into oil. The leaves again are used for thatching, baskets, mats, &c., and for deeds and documents, being far more durable in this moist climate than the paper in ordinary use. Mr. (now Sir Charles) Lawson, in his interesting book on Cochin, published nearly 30 years ago, has a chapter on the coconut tree which reads like a poem. This chapter he concludes with the following apt quotation regarding the marvellous yield of this wonder of Nature:—

"Clothing, meat, trencher, drink and can,

Boat, cable, sail, mast, needle, all in one."

At Quilon we stop for a couple of hours for breakfast and in order to pay a visit to the principal forest officer. Here the waterway is diminished to a narrow channel, and about 15 miles further the canal passes through two tunnels each about a couple of hundred yards long. These tunnels form a really very fine engineering work, and were built at a very great cost so as to complete the connection of the waterway to Trevandrum. We pass through them about sunset, and arrive at Trevandrum during the night. When we wake next morning the boat is moored alongside the wharf and a carriage is waiting to take us to the Club, where accommodation has been provided. Trevandrum is a prosperous-looking town: the houses are well and substantially built. It has more the look of a hill-station than a sea-coast town. The sea is not visible and the houses are scattered over a series of small hills, most of which are covered with trees through which the houses appear. At the Club we found a letter from the Dewan fixing an hour for an

interview that same morning, so we at once drove there. Mr. Rama Row, the Dewan of Travancore, is a portly, good-natured-looking gentleman of middle age. He has a very intelligent face with bright eyes. Almost the whole of his service has been spent in Travancore, where he is greatly respected, having risen from the subordinate ranks to his present position. He showed a very great interest in the road which it was proposed to make and promised to give the matter his early attention. Roads are one of the Dewan's hobbies, and he has already done a great deal towards opening out the country. On our asking whether we could speak to the Maharajah we were told that all that was necessary was to write to him direct. This we did after leaving the Dewan, and at once received an answer from the Maharaja himself appointing the next morning for an interview.

The Maharaja's palace is situated in the middle of the town. It consists of a series of buildings with no very great pretensions. There is a fine Durbar Hall, but the building in which the Maharaja resides is one of the smallest. Almost immediately after our arrival in the courtyard the Maharaja appeared at the door of this building and, holding out his hand, asked us to come in. He was simply but tastefully dressed in a long coat and trousers of a quiet but pretty pattern, with very few jewels or ornaments. He is a young-looking man—as far I could judge—25 or 26 years of age. He has a most intelligent-looking face with a very pleasant smile. He led the way upstairs to a handsomely but not gorgeously furnished room, and sitting down by our side spoke very pleasantly for about a quarter of an hour. He evidently seemed to take a great interest in his country and its affairs, and was thoroughly conversant with all that went on. We mentioned to him the road that was required, and he promised to look into the matter with his Dewan and give help if possible. We then took our leave, much pleased with so agreeable a specimen of an Indian Prince.

The Dewan having kindly sent a copy of his last Administration Report (for 1887-88) I may as well give here a few figures regarding this prosperous little State. When the year under review opened there was a balance to the good of more than 58 lakhs of rupees. The revenue during the year from all sources was R115,264 and the expenditure R69,92,458, leaving a surplus of nearly one lakh and a quarter to be carried to the credit balance. The principal items of revenue are from land 19 lakhs, and salt nearly 16 lakhs. Then come customs, 5 lakhs; law and justice, 4½ lakhs; and various other items of a miscellaneous nature. Under expenditure no less than 12 lakhs are spent on religious and charitable institutions and ceremonies. The troops and military establishment cost about 1½ lakhs. The expenditure on the palace is only R571,131 and the subsidy to the British Government something over 8 lakhs. More than two lakhs are spent on forests, but as the revenue from this source is nearly 4½ lakhs the return is over cent per cent. Under almost every head there is a credit balance, and the general administration seems to be cheaply managed. The actual expenditure of the year showed an increase of nearly 3½ lakhs, but this was due to extraordinary charges for certain ceremonies and for the Maharaja's journey to Madras and Bombay. The actual normal expenses showed a decrease "of fully one-fourth of a lakh, notwithstanding that over R69,000 have been additionally spent on public works" and various other improvements carried out. Under receipts, on the other hand, there was an increase on the previous year's revenue of R1,88,837, and "is by far the highest revenue yet

attained. Looking over the several items, it is satisfactory to note that almost all the heads have contributed an increase, the largest being from salt, land revenue, tobacco, cardamoms, customs, forest, and akkari and opium." Space will not allow me to go greatly into the details of this interesting Report, and I will only notice one other item, viz., trade.

The entire trade of the country, exclusive of transactions on account of Government, amounted in value to R1,70,41,878, being an increase of nearly 7½ lakhs on the trade of the previous year. Out of this amount nearly 38 lakhs was carried by sea, nearly 45 by backwater and 15½ by land. These figures show the enormous advantage of the excellent inland waterway. The wonderful coconut tree, with its various products of copra, oil, coir, fibre and nuts, yields for trade purposes goods valued at no less than 54 lakhs, and shows an increase on the previous year's transactions of from 20 to 25 per cent. The total value of the exports being R98,15,422, the coconut tree yields considerably more than one-half of the total produce exported. Imports amount to 72½ lakhs, thus showing a credit balance in favour of the country of nearly 26 lakhs. The chief items of import are piece-goods, rice and paddy and tobacco. An enormous quantity of tobacco seems to be consumed, the value being put at 24½ lakhs. Although there is so much water the country is not able to produce enough rice for its requirements, and the imports of rice and paddy amount in value to more than 13½ lakhs. Piece-goods to the value of more than 10 lakhs were imported. The total value of the imports shows, however, a decrease on the previous year of a little more than one lakh. Altogether the Report is a most interesting one, and shows how great a state of prosperity can be gained by a Native State when under good management.

There is a very fine museum in Trevandrum, built of stone in imitation of the Hindu work. It stands in the middle of some fine gardens and is visited during the year by more than 200,000 persons. There is in the museum a good collection of birds, animals and curiosities, but there is room for a great deal more than is at present to be seen.

After a pleasant stay of two days in Trevandrum we started in a bullock-transit for Tinnevely, a distance of about 100 miles. There was a good road the whole way and the journey was done in about 30 hours. About half-way we passed through the hills which shut Travancore off from the rest of India. They are here much lower than they were further north, but far away in the distance we could see dim masses of hill giants with their crests covered by lowering clouds, for the monsoon had now fairly broken. From Tinnevely we took the train to Madura, a journey lasting about six hours. At the latter town we stopped for two days in order to visit the celebrated buildings. The ancient magnificent palace of Tirumal Naick is now almost completely restored and ready for the public offices which are to be located there. It is certainly a splendid specimen of old Hindu architecture. It consists of an enormous courtyard surrounded by massive columns enclosing covered verandahs, and at the further end is a magnificent Durbar Hall. It is well that this relic of Hinduism should have been restored: but I cannot say much for the taste with which the restoration has been carried out. Amongst other things two tawdry pepper-box-looking towers have been added which look ludicrous by the side of columns and arches of such massive grandeur. The marvellous temple built in honour of the marriage of Shiva with Minarkshi, a local goddess, needs no description of mine. Its existence

is a specimen of the talent with which the Brahmins knew how to popularise their religion and to graft it on the customs and traditions of the aboriginal races which they found in India. One word, however regarding the Tunkam, or restored palace of an old Madura queen, which now forms the residence of the Collector. The building was restored by a native and the result is something infinitely more tasteful than what has been produced in Tirumal Naick's place. Native taste has known how to blend colours and introduce ornamentations in perfect harmony with the old building, and the whole now forms a perfect gem. But our trip is now nearly over. From Madura we go by rail to Tanjore a journey of about 15 hours. There we spend a day in the old temple and then back to Madras, and heat, work and worry. But the eight weeks spent form a pleasant recollection to look back upon, and I wish that I may have made my description of them one half as pleasant as they were to me. REKAB.

—*Pioneer.*

SISAL HEMP:—A PROFITABLE INDUSTRY.

We are indebted to a correspondent who favours us as follows:—

"You take such an interest in all agricultural matters that I send you a part of a letter from the present Administrator of Bahamas about Sisal Hemp. From all I hear it is the honest money-making thing of the present day, and the "dead and alive" West Indians will perhaps bring it to Ceylon as they did coffee."

No, no, what a young Aberdonian brought to us from Jamaica was the West Indian plan of cultivating coffee. Here is the extract about Sisal Hemp:—

"—has embarked in the Sisal culture, 1,000 acres of pine forest near Adelaide, has commenced operations, and a few days ago the agent of an English syndicate, I hear, offered him £2,000 for the land as it is now. He only paid 5s an acre for it. There is a rush from abroad and the price of land has gone up; the Government will raise it from 5s to 10s per acre. The fibre extracted is pronounced unequalled and the demand will for years exceed very largely the supply. There is no doubt that it is a safe investment. Our pineapple industry is so precarious; do you know that since the application of Forester's fertilizers to the wasted lands of Eleuthera, the pine crops have been enormous and *over-productive*: the results! Cuba has gone deeply into the cultivation and Florida is making rapid strides in that direction, so that Eleuthera will be handicapped terribly in this industry. Jamaica, Cuba and Florida are running us in the matter of oranges, and \$3 per thousand can only be looked for. The disappointing feature about the Sisal Hemp culture is that the small holders of land, the negroes, cannot be awakened up; the bounty offered by the Legislature of 1s 2d per lb. of not less than 1 ton weight exported does not stimulate them: the consequence is that the outsiders, large and wealthy companies and individuals aroused by the advantages offered will absorb the land and suck the Treasury. The bounty is only for 5 years, and before the industry is started on gigantic lines and the yield be proportionate the act will expire *never* to be renewed."

A CINCHONA GROWERS' SYNDICATE.

Baron G. von Rosenberg, one of the leading cinchona planters in Southern India, is making a determined attempt to create a combination among cinchona growers in India, Java, and Ceylon, and, as a first step towards the accomplishment of this object, has issued an appeal to his fellow-planters throughout the Eastern world to join him in his crusade. Were it not for Baron Rosenberg's prominent position as a planter, and the probability that he has taken steps to ascertain the views of his colleagues in Southern India before

initiating what looks more like a serious attempt at forming a ring than a mere occasional outpouring in the columns of a newspaper, his appeal would deserve less attention than it is sure to excite at present. In any case, the moment seems singularly inopportune to set on foot fresh industrial combinations. Only a few weeks ago we had occasion to point out the failure of several attempts at the creation of rings, and, on the very day that the mail brought us Baron Rosenberg's appeal, news came of what looks like the beginning of the end of the iodine convention, which was started under much more satisfactory auspices than are at all likely to obtain in the case of a cinchona combination. Baron Rosenberg's appeal commences by asserting that in British India and Java, and probably in Ceylon, there are still planters left to whom a remunerative market for cinchona is a matter of life or death. He does not count himself among that number, as he grows barks equalling from 3 to 6½ per cent of quinine sulphate, which, even at the present range of prices, are still worth shipping. Moreover, personally he is in a position to hold back, if need be, until such time as the poorer class barks which now swamp the market shall have ceased to come over. But he is anxious about those weaker brethren who only grow poor barks, and are now on the way to the "orful dogs. Hence he chivalrously springs into the breach on their behalf and suggests the creation of a force strong enough to assume the control of the market. To Baron Rosenberg's mind the operation seems rather a simple one, and if only his suggestions are adopted results will follow, "not at once, perhaps, but, by a cordial co-operation of the planters, in six months' time." But the first step is to sink immediate individual interest for the common good, as the formation of a ring is the only salvation of the planters. "Left alone," as the Baron graphically expresses it, "the planter becomes a sort of bullock, doing his daily round, taking his bark and cropping his coffee without reference to the state of the market, and later on lamenting the loss."

The proposed combination, it is said, will only comprise a few hundred (!) planters; it will most certainly receive the cordial support of merchants, brokers, and even of the purchasers of bark, and everybody will benefit by a rise in prices. The consumer, it is true, is not included in this happy circle; but then we are told that even now, judging by the prices charged by retail druggists, a fall or rise in quinine makes no odds to him, and, moreover, he must help himself, because, for the producers, charity begins at home. Looking at the matter from Baron Rosenberg's standpoint, we can only commend him for the public spirit with which he endeavours to improve his fellow-planters' position, but we are decidedly of opinion that this experiment at floating a combination which shall work upon a satisfactory basis will prove a disappointment, and is bound to fail as completely as, from the standpoint of public policy, it deserves to do. In the first place, the organiser of the would-be combination wishes to confine the ring to the planters of British India, Ceylon, and Java. The South American growers he treats as a negligible factor in the situation, and in doing so we are inclined to believe that he commits a serious, if not a fatal, mistake. It may be true that no appreciable amounts of uncultivated bark can be placed in the market, even if the unit were to rise to four or six times its present value, but we are inclined to believe that any pronounced advance would quickly call forth important shipments of bark from the Bolivian plantations, and not improbably also from the Central American forests, whence we obtained such immense quantities seven or eight years ago. Looking through our own reports of the bark sales held in London during the present year, we find that during the first seven months of 1889 over 200,000 lb. of cultivated Bolivian calisaya quills (that is not including flat yellow bark) have been sold here by public auction, nearly all of this bark having been quite recently imported, and averaging fully 4½ per cent, if not more, of quinine sulphate. This fact goes some way to show what

we may expect from that quarter if once the cultivation there should receive an impetus from the knowledge that a "ring" had been formed between the Eastern growers. Would it be safe, then, under these circumstances to ignore the Bolivian planters in the formation of a convention? On the other hand would it be possible to secure their adhesion or compel their observance of the rules of a syndicate? Besides, even if this difficulty were overcome, others of equal or still greater importance would remain to be solved. The basis of Baron Rosenberg's proposal is that all planters entering the convention shall pledge themselves to harvest and export only half of their estimated output. Now there must be in India, Ceylon, and Java together at least 300 planters who are growing cinchona on private estates, and the Dutch Government plantations would almost certainly have to be counted among the opposers rather than the backers of the scheme, for it is incredible that the Dutch Colonial Government should enter into any bargain such as that now proposed. And how are all these public planters, whose estates are many thousands of miles apart from one another, and who possess not even a common central market, to be brought under control? By what means, should they be proved to have infringed the rules of the combination, are they to be punished in such a manner as to prevent the repetition of their offence? Baron Rosenberg himself acknowledges that there would be a number of black sheep professing adherence to the ring, but secretly transgressing its rules, though as a planter, and speaking of course with a greater personal knowledge of his colleagues than we can lay claim to, he believes that the delinquents would be few. We can only express the hope that his kindly opinions of his fellow-creatures may never be put to the severe strain which the establishment of a combination would entail. The *Ceylon Observer* in commenting upon the proposed syndicate justly observes that the planters, after all, are frequently not the masters of the situation. Many of them are not in a position for want of the necessary capital to leave half their bark unstripped while they can still get a small margin for it in Europe, and we may add that with the creation of a syndicate temptation would in many instances be irresistible to forego the opportunity of making a good stroke on the quiet. Moreover, the leading Java planters would certainly, and we should think properly, be indisposed to enter into an alliance with their Ceylon *confères* with the express object of helping the growers of the poorer barks to keep their heads above water. They hold the better end of the stick by a long way. They, with some of their Indian colleagues and a few South American planters, mostly grow rich barks, which they will still be able to ship at a profit when exporting must cease to become profitable to the Ceylon growers of poor cinchonas. The glut and collapse of the market are mainly caused through the action of the latter; what, therefore, could better suit the cultivators of the higher barks than that those Ceylon growers who now spoil the market with their poor stuff should be weeded out? As to Baron Rosenberg's anticipation that under his scheme the "present leaden tone of the market would give place to one of elasticity and speculation, both good for the producers," we confess that we cannot agree with him in the belief that the planters would reap any benefit from a revival of great speculative energy in the cinchona market. A leaden tone may not be pleasant, but a mercurial one is worse, as it would simply reduce planters to the position of tools of the London "bear" and "bull" speculators. The question of the production of cinchona, in fact, must work out its own salvation. The bark growers, through their unbridled eagerness to secure a share in a profitable culture, coupled with their disregard of the quinine consuming capacities of mankind, have brought their present plight upon themselves. What we now witness in the cinchona trade we have seen before in the cinnamon market, and we shall see in all probability in the tea trade a few years hence. It does not require the gift of prophecy to foretell that any attempt to stem the natural consequences of such recklessness must fail. By and by, no doubt, when most of the

Ceylon and Java planters shall have uprooted their trees because they did no longer pay to keep, we may see an improvement in cinchona, and we trust that when that times comes Baron Rosenberg may be one of the favourite planters whom survival shall indicate as among the fittest of their species. If we may presume to offer him any advice now from our point of impartial observers of the market, it is to let well alone, and to leave his more unfavourably placed brethren to fight their own battles. Why should he go out of his way to bolster up the weaker ones who are bound to go to the wall? and why, in the name of common sense, should he aspire to the historic part of the "fond ally that fights for all, but ever fights in vain"?—*Chemist & Druggist*, August 10th.

CINCHONA CULTIVATION IN JAVA.

The report by Mr. van Romunde, Director of the Government Cinchona Enterprise in Java, for the second quarter of 1889, has just reached us. It is dated Tirtasari, 10th July 1889, and runs:—

The weather continued very rainy during the past quarter. After the long-continued drought in the second half of the year 1888 and the extremely small amount of rain in the months of January and February of this year the wet weather in the past quarter was very favorable for the growth of the plants, and the plantations have therefore during the last few months grown very well everywhere. The upkeep of young plantations necessitated a good deal of manual labor on account of the rapid growth of upspringing weeds. It was intended to carry out in the second quarter of this year a vigorous working of the soil in the older gardens that were already producing, and after some days of dry weather in April a beginning was made with this, but the intention had to be soon abandoned on account of the falling of continuous and sometimes very heavy showers of rain. The old plantations were therefore chiefly and only very superficially operated upon, and that where the growth of weeds was too vigorous. While during the past few years there has been no cause for complaint with respect to supply of labour, in the past quarter the number of work-people was very small. The same phenomenon was also experienced on the private estates in the vicinity of the Government enterprise. In order to retain the fixed staff and to insure the carrying out of urgently needed operations, the daily tasks were considerably reduced, a method which was chosen rather than the raising of the commonly recognized pay of 20 cents per diem, because an increase of task work can be more easily carried out than the lowering of a day's pay once recognized. Meanwhile, in order to yield as little as possible to the pretty general pressure towards an increase of wages or what is much the same thing a decrease of tasks, operations were restricted to the absolutely necessary, and the gathering of cinchona bark on most of the establishments was therefore as much as possible stopped in June, or at least temporarily restricted to the absolutely essential, which can be done without harm and without inconvenience, now that satisfactory means for drying by sun-heat and scientific apparatus are everywhere available, to gather a large quantity of bark during the course of this year. From the crop of this year some 370,000 half-kilograms of bark have been obtained, of which by the end of June 312,036 pounds had been dispatched to Tandjong-Priok. The crop of 1889 was estimated at the beginning of this year at 900,000 half-kilograms of bark. That outcome would certainly have been largely exceeded were it not that a considerable decrease in price, of about 25 per cent, had intervened. That decrease in price has been the cause of more and more bark of young branches and twigs being left in the plantations. Should the decrease in value continue, only quills of druggists' bark of the desired form and of handsome appearance can be sent, so as to still realize a paying price. But in that case the quantity of bark to be obtained will undergo a material diminution. In consequence of the long-continued rain many of the

older trees especially in close plantations were again attacked by canker. Where the disease confined itself to branches, these were sawn off, and where the stem was attacked the whole tree was dug out and stripped. As usual the disease was most noticed in the graft plantations at Tirtasari. On 21st February, 21st March and 22nd May sales of cinchona bark of the crop of 1888 were held at Amsterdam. The average prices at these sales were 28⁴⁶, 26⁷³ and 32⁸⁰ cents per half-kilogram of bark. The unit prices—reckoned per half-kilogram bark and per cent quinine sulphate—were, according to the reports, at the sales of 2nd May and 13th June respectively 7½ and 7 cents.

The number of plants and trees of all varieties in the Government cinchona plantations at the end of June was as follows:—In the nurseries: 1,205,000 ledgeriana (including 21,000 grafts); 140,000 succirubra. In the open: 1,195,000 ledgeriana (including 225,000 grafts and cuttings, and exclusive of the more or less 3,000 original ledgerianas); 3,400 calisava and hasskarliana; 637,000 succirubra and caloptera; 73,900 officinalis; 750 lancifolia (including 250 *C. pitayensis*). Grand total 3,255,050.

TEA AND THE TRADE OF SHANGHAI.

There is not very much of striking interest in Mr. Hughes's report on the trade of Shanghai. Of tea Mr. Hughes has not very much that is new to tell us, except the curious fact that there is a growing increase in the export to Bombay, for use in Afghanistan and Persia! Surely the Kangra Valley planters will not submit quietly to this successful competition against their local produce. It is, no doubt, a question mainly of preparation—of higher firing and fermentation, to enable the leaf to support the longer journey. The statistics, price, and quality of the general crop have been discussed so often in the course of the season that it is hardly worth while going again over the ground. The question of chief interest is whether the growers are awaking to the necessity of more careful preparation. Mr. Hughes's information is that, so far, they were not; and that the profitable results of the last crop tended to confirm them in their error.

TEA.—On this subject reliable information will be found in the following memorandum which has been kindly supplied by a merchant of great knowledge and experience:—“The tea trade from the North of China for the season 1888-9 is more than usually interesting from the exceptional occurrences which have happened. In the first place, the customary facilities given by native bankers to curers of the leaf were very much restricted during the spring of 1888, and none but well known men could obtain even moderate advances; consequently there was much less money than is ordinarily the case in the producing districts to buy leaf. The first few days of the picking-time were gloriously fine, and a fair quantity of leaf was gathered in prime condition, but on about the fourth day unusually bad stormy weather set in, and the greater portion of the first crop was damaged or left on the trees unpicked. The result of these adverse circumstances was that the total yield of ‘first’ crop teas amounted to only about 31,000,000 lb. against nearly 50,000,000 lb. the previous year. The profits made by curers were very good, and made up for their losses of three or four previous seasons. Owing to a peculiar taint called by the trade ‘tarry’ or ‘smoky’ flavour, due to the primitive methods of preparing the tea for export, and which breaks down under any but the most favourable weather influences, most of the ‘first’ crop teas were unsuitable for the Russian markets, and the bulk of this crop found its way to England. The weather for picking and curing the second and third crops was very favourable, and it is many years since such good teas of this class were brought to market. It is a noticeable fact, as showing the extraordinary elasticity of the trade, that, notwithstanding the small production of ‘first’ crop teas, and the low prices ruling for low class teas, the yield of ‘second’ and ‘third’ crops was so augmented that the total export from the North of China to all consuming countries falls very little short of the previous year,

“GREEN TEAS.—The whole of this business is done from Shanghai. There are two distinct classes of green tea. One class, called Pingsuey, is made in Ninpo and its neighbourhood, and comprises nearly half of the total yield. These teas are always inferior to the other class known to the trade as country teas. Pingsueys this year were poor in make, and rather below average quality. They have proved a bad investment for natives and foreigners alike. Most of them went to the United States and Canada. Country teas, on the other hand, were above the average quality of the past few seasons, and although prices opened higher than most buyers expected they have given fair results throughout the season, and native dealers have participated in the profits. The crop of these fell some 30,000 half-chests, say 2,000,000 lb. short of the previous year, and shipments were well distributed between New York and London.

“The only new feature in the green tea trade is the rapid increase in the export to Bombay for use in Afghanistan and Persia. The descriptions sent are bold leaf teas known as Hysons, and shipments amount to nearly 3,000,000 lb., against about 2,000,000 the previous year.

“There is no sign of any attempt being likely to be made to improve the method of preparing teas for export, and the profitable results of the past season have tended to confirm the natives in their opinion that there is no need for change. They will not see that the consumption of China tea in Great Britain continues to decrease, and the only hope for it to regain its position is to improve its manufacture.

“Duties and inland taxation remain unchanged, with no prospect of any reduction.

“Preparations for the next black tea crop, the picking of which commenced in April, 1889, are on a scale fully equal to those for 1888. Many facilities are being offered by native middlemen to the curers recklessly. The number of curing hong in the producing districts are already nearly 50 per cent. over last year's figures, and everything points to the preparation of one of the largest crops on record.”—*J. & C. Express*

CONSULAR REPORTS: AMSTERDAM.

TRADE WITH JAVA.

The following paragraphs are taken from Consul Robinson's report on the trade and navigation at Amsterdam in the year 1888:—

Trade with the Dutch East Indies was remarkably brisk, the exports from Holland, especially, being so greatly increased that the regular lines of steamers found it difficult to keep pace with the demand for room.

COFFEE.—As anticipated, there was a considerable falling off in the general importation of coffee in 1888. The total summing up 773,100 bags, as against 1,098,000 in 1887. The reduction is almost altogether in the importation from the Government Java plantations. The Netherlands Trading Company, as agents for the Government, imported 306,000 bags of Java coffee in 1888, as compared with 622,000 bags in 1887. The visible stock on Dec. 31st, 1888, was 367,800 bags, as compared with 622,000 bags at the end of 1887. Prices fell from 9d to 6½d per pound for good ordinary Java in March and April, 1888, thus discounting the anticipated large Brazil crop 1888-9, but the demand for consumption being large, on account of the great reduction in stocks, a reaction took place, bringing the prices to 9½d per pound in November, and closing the year at about 9d per pound.

Though the production on the Government plantations in Java appears to be stationary, a large extent of waste land is being taken into cultivation by private enterprise, and the accounts of the health of the plant in Java are more encouraging.

SUGAR.—Of Java sugar less than 100 tons came to Amsterdam in 1888.

TEA.—The import of Java Tea reached 28,619 quarter chests, against only 3,423 quarter chests of China tea. Prices were low, the quality of Java tea steadily improving, and consumption increasing, while that of China tea loses ground.

TIN.—The final collapse of the French Syndicate in this article brought about a sudden drop in prices from £163 per ton for Banca to £81 10s. followed, however, by a reaction which left the price at about a normal figure, say £98 to £101 per ton. The stock at the end of the year was 48,198 blocks against 35,937 blocks, in 1887 and 47,216 in 1886.

TOBACCO.—This staple article formed an exception to the general course of trade in 1888, and was on the whole very disappointing to importers. The quality of the Sumatra crop was not so good as in previous years, the plant not having fully developed itself in time; there was, in consequence, a much larger quantity of dark-coloured and second class tobaccos among the importations, and the light-coloured sorts, which had commanded such very high prices, were comparatively scarce. America, the largest buyer of these finer sorts, did not find the quality she required in our market. There was a large crop, and the few lots of really fine quality fetched high rates, but the large proportion of middling and inferior sorts had to be sold at rates which were exceedingly discouraging to importers. The average price per pound English obtained for the whole crop fell from 2s 4d per lb in 1887, to 1s 9½d per lb in 1888, being a reduction of over 20 per cent. Although the more favourably situated plantations still gave very good results, as is shown by the dividends paid for 1888 by some of our tobacco plantation companies, so serious a drop has jeopardised the existence of many undertakings which were already struggling with the difficulties of unsuitable soil and indifferent quality of the produce, and already some of the latter enterprises of this description have been liquidated with very serious loss. A small lot of Borneo tobacco was imported and sold at a satisfactory price, 1s 11d per lb. There are now six plantations in Borneo, principally established by English capitalists, either alone or in combination with Dutch planters. The Java crop was better in quality than that of Sumatra, and fetched, proportionately, better prices—*L. and C. Express.*

“ENGLISH CONSUMERS PREFERRING INDIAN AND CEYLON, TO CHINA, TEA.”—Such is the conclusion openly avowed by the London *Times* in its review of the latest Board of Trade returns—and coming from such a quarter, we need not say that the avowal is of importance in benefiting the credit of both India and Ceylon. Here is the passage:—

The landings of tea show a great diminution, owing to the shipments from China being only 10,943,000 lb. against 25,570,000 lb. Indian and Ceylon teas are now much preferred by consumers, as is shown by the fact that, of 107,000,000 lb. taken out of bond during the past seven months, over 70,000,000 lb. were Indian and Ceylon, and only about 36,000,000 lb. Chinese.

TWO FRAUDS PREVALENT IN REGARD TO COFFEE.—The first consists in improving raw coffee spoiled by seawater, and sold for almost nothing. When received they are black and most unattractive. But skilful gentlemen manage to make them as good as new apparently. The beans are first soaked in water to remove the salt and rank taste; they are next bleached with lime-water, and finally coloured green or yellow to imitate various brands. It is almost unnecessary to remark that such beans have only the outside appearance of coffee; they have lost all taste and flavour. A simple method to detect the fraud is to take the specific gravity by means of the volumetometer. Pure coffee never shows a specific gravity below 1.000, and is generally above, while repaired coffee is much lighter. The other fraud is accomplished with roasted coffee, by wetting it with water while still hot. In the warm state coffee will thus absorb as much as 20 per cent of moisture, and yet remain hard and brittle. It only needs a little facing with some oil to appear excellent. The fraud is found by drying the bean at 110° C., when it should not lose more than 2 to 5 per cent of water.—*Chemist and Druggist.*

TEA CROP ESTIMATES: 1889-90.—While Mr. Rutherford estimates an export of 43 million lb. in 1889-90 and we consider 41 millions a safer reckoning, here is what a “planting correspondent” of the local “Times” writes:—

“I read Mr. Rutherford’s estimate with great interest. Were the figures not his, however, I should be inclined to say that they understated matters. 330 lb. an acre for an average yield off *old* tea is not high and ought to be exceeded. So ought 250 lb. off 48,000 acres 4 to 5 years old. I should not be surprised if we obtained nearer 50 million lb. than 43,000,000.”

This writer forgets that tea on a good deal of old coffee land is included in the areas estimated for. But here again is what an experienced upcountry planter writes to us on the subject of next year’s estimate:—

“Rutherford’s estimate 1889-90: not being here, he is not aware of the change in the style of plucking: fully 10 per cent finer than it was. So that knocks off 4,000,000 lb. He was lucky this year in the dry weather of 1888-89 which brought the hill estates (the bulk of the tea) to the front, and so much of the last of the tea made season 1887-88 held back till 1888-89—from lack of shipping. There will not be anything like that in beginning of 1889-90. A lot of tea is being now pruned, and that in the hill-country means 4 to 6 months’ light flushing. You may safely knock 4,000,000 lb. off Rutherford’s estimate.”

MICA AND PLUMBAGO.—A planter sent us a remarkably solid and dark-coloured piece of mica with the following remarks:—

“I gather from the *Observer* that a dark kind of mica, or talc, is often a surface indication of plumbago. I hope you will take a look at some I am taking the liberty of sending by today’s post, and if convenient get the opinion of some mining expert. I don’t remember to have seen before quite the same kind of mica and in such large quantities as it is to be found on this estate. I must differ from the *Observer* with regard to plumbago being of vegetable production; had such been the case it would have been found in conformity with the strata and not in veins. I hardly think the earth was in condition during the gneissic period to produce vegetation, at any rate of the kind we have now. I believe plumbago to be a carburet of iron. The carburet of iron theory has been long exploded, and no wonder, for some of the finer Ceylon and Canadian graphites analyze to 98 per cent pure carbon. Plumbago is of vegetable origin and one of the earliest formations in our globe. Our scientific referee replies to our reference thus:—

“The specimen of mica you sent me (and which I now return) is doubtless a very solid block, but I cannot see a trace of plumbago about it. It is certainly heavy, but then mica is a good deal heavier than plumbago, as you will see by looking up their Sp. Gravity. Mr. ———’s ideas about plumbago are rather unique. Let him dissolve the iron out of pounded plumbago and what does he make out the remnant to be? Iron is doubtless not chemically combined with plumbago, but even if it was, from what sort of matter was all that carbon derived? The argument that if plumbago has been derived from vegetable matter it would be found in strata is very wrong. Mr. ——— seems to forget that our rocks owing to metamorphic action are very much changed.” Mica is composed of minerals which have no affinity to plumbago, such as silicates of alumina, potash, soda, oxides of iron and manganese, &c. Large plates of mica are useful for lanterns and small flakes in the use of the microscope, and in the United States “mica grease” for machinery seems largely used, more even than plumbago as a lubricant. We did not mention mica as an indication of plumbago, but that certain flaky forms of the latter mineral gave rise to a wild native idea that mica became metamorphosed into plumbago. The rock in which mica so largely abounds is probably mica schist.

COFFEE AND TEA IN VICTORIA.—Only through the English papers by this mail, do we learn that, in consequence of the improved financial position of the Colony, the Premier of Victoria was able on Tuesday (July 30th) to announce the abolition of the coffee duty and the reduction of the duty on tea to 1d. per lb.

TEA IN INDIA.—The following is taken from the printed report on a successful tea garden in the Terai, just issued: "It (the garden) has seen its best days, and is not likely to pay much, now that plains' teas are so abundant as to glut the market. It has laboured under one disadvantage, it has not been coached by a Calcutta Agency House. Had it had the benefit of this skilled control, who could say what the profit to the proprietors might have been? As it is, I believe, they have divided amongst them over 2½ lakhs, and we have a working capital of nearly £20,000." *M. Mail.*

TEA PLANTING IN CEYLON.—We have received the following from a correspondent in London:—"The editor of the *Pictorial World* has accepted a series of eighteen sketches on tea planting in Ceylon for publication in his paper, executed by Mr. Charles Rea during a recent visit to the island, which will appear at no very distant date. They comprise views of the bungalow, factory, estate, and show the whole process of tea-making from plucking to dispatch to the railway, together with a short description of the domestic life of the planter, his management of Tamil coolies, cultivation of tea, and future prospects of this industry."

TEA IN MOROCCO.—The Consular report on the trade of Morocco mentions that the tea trade, which continues entirely with England, shows a general improvement, which is most marked at Larache, the value of tea imported at all the ports amounting to £39,378, as against £26,555 in 1887. The same classes of Hysons and Young Hysons, of from 7d. to 1s. 5d. per lb., are still in favour. The Vice-Consul at Larache also reports:—"Tea shows the satisfactory increase of 400 boxes or half-chests, but as the value has not risen in proportion, the presumption is that the quality is inferior; Cheap sugar has enormously stimulated the consumption of this beverage, in which the town Moor is a true connoisseur, but the country people, who are now contracting the habit (no longer prohibited by its cost), are satisfied with a very inferior quality."—*L. & C. Express*, Aug. 16th.

COFFEE IN JAVA.—According to the annual report of the Samarang Agricultural Company the business is limited to the working of a Coffee land in Kadoe and one in Solo (Java), transferred to the Company by the Samarang Trading Society. The undertaking in Kadoe has suffered much from disease of the leaves, notwithstanding all the measures that have been used to check it. The latest reports, however, are more favourable. The company has also one Indigo undertaking, the results of which were tolerably satisfactory. The report refers to the company's possession of a seven-eighths' share in a sugar manufactory, situated in Solo, but the serah disease has caused considerable damage, resulting in a loss of f.31,838. A better result is expected in the present year. From the profit and loss account it appears that there is a loss of f.3,121, which will be carried to next account. The *States Gazette* of the 24th inst. notifies the floating of the Agricultural Company "Penampan," in this city, which purposes to work the Coffee and Cinchona undertaking in Ngrow district Kediri (Java). The capital amounts to 660,000, in shares of 1,000 each.—*Amsterdam Cor.*, (*L. and C. Express*, August 23rd.)

FLAX IN NEW ZEALAND.—Flax owners are (according to the *New Zealand Times* of May 16) getting very handsome royalties just now. Rumour says the Oroua Estate receives £2,800 a year royalty on a weed (Phormium-tenax) that they have spent much money trying to eradicate. Another big West Coast estate is getting over £1000 a year in royalties. The favourite form of Flax royalty is a rent of £14 per shipper per month for a day of ten hours, whether the mill be working or idle. Some landlords charge a royalty of 7s. 6d. to 10s. per ton of green Flax, and even higher prices are mentioned.—*Gardeners' Chronicle.*

CINCHONA PROSPECTS AND WHAT THE REGULATION OF SHIPMENTS MIGHT DO.—With reference to the discussion in our columns started by Baron von Rosenberg, the following extract from the letter of a well-informed London House to their Colombo correspondents has been sent to us:—"If the Syndicate of growers of bark again talked of and brought out in the *Observer* as an entirely new idea were to be established, we have no doubt a rise of 100 per cent could be established in a short time, but we don't think it will be done." This remark would seem to apply to Ceylon alone, without reference to India or Java, much less to growers in Bolivia—who are brought forward as a bugbear by the *Chemist and Druggist* in a long article which will be found on page 252. And there can be little doubt that if five or six instead of nine or ten million lb. of bark were sent from Ceylon in a season, the rate paid for the lower quantity would be much enhanced. But Ceylon planters would inevitably ask that Indian and Java planters kept down their exports also. Now what has been suggested to us by responsible men here as a feasible means of operating would be by the establishment of a Store Syndicate in Colombo prepared to regulate shipments in equal proportions according to receipts and to meet the planters' pecuniary exigencies by advancing about 60 per cent of the current value of the bark stored. Such is the proposal made to us in all good faith. It is for the planters of Uva at their next meeting to give their opinion of it, they being the chief holders of bark. The very announcement of such an arrangement would, it is said, better the market.—Meantime we have to do with largely increased exports of bark during the past few weeks after an encouraging lull; but our London friends should note that the shipments are mainly of bark stored in Colombo and that local stores are now said to be nearly depleted. The following figures up to the latest date available in this sense are instructive:—

CINCHONA BARK

CARRIED BY RAILWAY FROM 1ST JUNE TO 22ND AUGUST.

	1889.		1888.		1887.

To the Editor.

BARON VON ROSENBERG ON A PLANTING
SYNDICATE TO REGULATE THE CINCHONA
BARK CROPS.

Devikulam, Aug. 9th, 1889.

DEAR SIR,—Many thanks for yours of 15th ult. You will pardon my not having answered it sooner, as I have been away. I was certainly pleased to see the prominence you gave to my letter, and can only hope that planters will give it the same consideration.

The answer you subsequently gave from a correspondent (G. A. D.) and sent to me was remarkable. It was short, concise and to the point—but was it true?

I can hardly believe that 9 millions of lb. are taken in Ceylon from dying trees (most of the trees that are injurious to other cultivation have already been uprooted); but if it be so *tant mieux pour nous*, for there will not be a tree left in Ceylon in a couple of years.

Nor is it a fact that "the cheapest storage in the world is procurable in Colombo." Consignees in London store for nothing, and so do our agents at Tuticorin. Supply and demand is a thing the merest tyro can write about. In answer I might indicate that the elasticity of the market has been damaged beyond the mere question of supply and demand by the power the "bears" have got over the quinine market especially on the Continent and in America. This is totally unwarranted by stocks of bark or quinine, and that especially as the figures in the latter, being fluctuating, are always over-estimated. But the fact is there, and after ever so small a rise, bears will send down their market again immediately until stocks are actually depleted. I know that the unit will go up; I know it as well as G. A. D.; but I wish to support a rising market if possible and help the quinine manufacturers to join hands with us planters in ousting mere speculation. At present it hardly pays manufacturers to manufacture, and were it not for the often disorganization of producers, it would not pay them at all. The only way they make it pay is this. Bark of low analysis, analysing say 1.45 per cent, is only bought in at the unit rate for one per cent, *i. e.* they clear nearly half a unit. This of course cannot be done with bark of a high analysis, as, owing to one lb. of bark analysing 6 per cent and 1 lb. bark analysing 1½ per cent costing the same to obtain the sulphate, a competition sets in for good barks.

Nor could it be the cause if the market were elastic; there would then be as much competition for the low as for the best sorts and the bark analysing 1.45 would probably fetch the unit value for 1.30. And it is especially necessary for cinchona planters to raise the tone of the market. A rise in the price of quinine would I think be even productive of consumption. The millions of the lower orders, on whom consumption depends, would rather buy a dear than a cheap drug: they don't believe in a cheap road to health and life! The chemists and druggists too, that important body domineering over physicians, would rather sell an expensive drug on which their commission amounts to more.

Nor must it be forgotten that antifebrine and especially antipyrin are slowly but surely undermining the market for quinine. It may take years for them to oust it, but they will certainly interfere with the increase in consumption. The time to act therefore

is certainly now, while as yet the rivalry is trivial. But if *mes confrères* are not willing to act, well I shall suffer less than they are mostly doing already. That this is not mere blarney, you can ascertain from my agents at home. Messrs. MacFadyen & Co. I can, on the prices I obtain, work my estates *thoroughly* and yet net a good profit. Nor are all my trees dying out as G. A. D.'s seem to be.

However I like G. A. D., and I wish he could see his way to work with me, for he is concise and I'm afraid I am not. If he be a *bona fide* cinchona planter, he will no doubt sooner or later come round to my view, I am afraid—later.

No, action must begin in Ceylon: Ceylon still exports the largest amount of bark, and very good bark it is some of it, not such as is obtained by uprooting diseased trees, or a tree here and there interfering with tea and open to the sun. If your Ceylon men will adopt the measure I have advocated, let them do so; they could almost compel India and Java to follow in their train.

I could however easily obtain number of estates and their acreages and probable export in India. The Wynaad Association is of course the principal one to reckon with, and I have already sent them your article and my letter.

Negotiations however must precede in and proceed from Ceylon. In Java I have no correspondents, but I would willingly correspond with the Planters' Associations there (in French or German, *ça m'est égal*) provided that a basis for operations in Java were first formed by co-operation in India and Ceylon.

But to give you an idea of the practical working. We up here on the high ranges of Travancore have some 1,634 acres in cinchona, most of it good (I have made allowance for neglected or frost-bitten clearings), some of it very good and giving analyses in bulk up to 6.88. Well we estimated next year's output in December last at 250 lb. per acre, we would therefore decide that—a fiat to the same effect having gone out from Ceylon and Wynaad Planters' Association and an adhesion having been secured from the Planters' Association in Uva, we would agree to put in only half our estimated bark, *i. e.* 125 lb. dry per acre, from say the beginning of next working season (with us it begins in April and goes on to November). If you think it would strengthen your Ceylon Association's hands, I would get this conditional (it must be conditional until the adherence is large) resolution passed by our Association meeting.

This of course is not thoroughly worked out, but if I myself can form a sufficient estimate, and I can easily do so, for our acreage up here, surely planters in Ceylon and the Wynaad could do the same.

One very important reason why planters should be willing to join is the fact that bark is all the better if left to renew from 18 months to two years: it improves during this time. They could therefore by yearly barking every other tree always have two years old renewed to take: the richer bark would therefore be a further gain to those I have already enumerated.

You ask me where my estates are situated. They are up here around Devikulam, and I am proprietor or principal part proprietor in four estates, Manalé, Lockhart, Kalamankai and Kedegumali. I am also a shareholder in the North Travancore Land Planting & Co., the owners of this district. —I am sir, yours faithfully, ROSENBERG.

P.S.—I may mention to you that I do not believe the actual execution of the plan would be necessary. I think the mere fact that an organization had been effected by cinchona planters and

that they could at any time bring this to bear upon the crop taking and export,—I say this fact and the knowledge of it among manufacturers and purchasers at home would, I think, be sufficient to right the market and make it elastic.

R.

AN APPEAL TO CINNAMON PLANTERS AGAINST ADVANCES.

10th August.

DEAR SIR,—Mr. William Jardine is to be congratulated on the success which has so far attended his efforts to suppress the trade in Chips. This success of his shows that Cinnamon Planters are willing to follow his lead. I therefore beg to pen this appeal to him, in the hope that it will be favourably entertained and that he will take it up with as much zeal and whole-heartedness as the anti-chips movement. The first movement appeals to our purse: this to our higher nature.

A pernicious practice has grown up amongst Cinnamon Planters of giving advances to their peelers, a practice which is indefensible and is therefore not on the same footing as coolie advances, which at the present day find their way into the hands of Chetties and not to the Coast of India. I say the practice is indefensible because there is no necessity for it, as our peelers are drawn from villages at our very doors so to speak. There is an exception, however, in the case of peelers drawn from the Southern Province, to whom a moderate advance to meet the cost of the journey and to be left with their families cannot be objected to. The Natives of this country, owing to the ease with which an existence can be eked out, are as a rule notoriously thriftless. No man who is both able and willing to work need starve for a single day, and to this is attributable to a great extent the non-provision made for times of sickness or for occasions when more money than suffices for their daily wants is necessary. All employers of labour have a solemn responsibility. They ought both by precept and example to make known to their employes those moral and social lessons which it is their high privilege to have had inculcated on them from their early youth. Not the least of these lessons is thrift. How do we encourage thrift? By pandering to the lower instincts of our peelers—for it is only of these that I am just now writing. Their earnings are very fair, but their employment is not continuous. It is confined only to the peeling season. In the intervals they are usually idle, and fall into those vices which are begotten of idleness. We encourage these by issuing advances to them, and at a time when the propensity to indulge in gambling and drink is at its highest during the Sinhalese New-Year. The necessity for advances will vanish if we encourage our peelers to engage in other works on our Estates during the intervals of peeling. They will then have continuous and remunerative employment all the year through, and will be able to avoid the Scylla of debt and the Charybdis of vice. That unity is strength is seldom more realized than in movements for the social and moral welfare of our fellowmen. Let all Cinnamon Planters unite to do away with the pernicious and immoral system of giving advances which are seldom or never put to right uses, and we will have taken one step—and an important one too—towards weaning our peelers from habits of idleness, vice and thriftlessness.

The subject has another and as serious an aspect. When peelers receive advances they usually enter into a contract to serve the Estates issuing them for a period not exceeding three years. They are, in fact, in a state of semi-slavery till the debt is liquidated. Those who have unfortunately been in debt know how depressing and demoralising it is. When once a man receives advances, his labour seems objectless. He receives nothing more for it than weekly advances, at least till his accounts are squared up a year hence. Many are the subterfuges resorted to obtain advances. Kanganies bring up bogus men for a consideration, who for the time being personate peelers, receive advances and sign the usual agreement. This is one of the moral effects of the system

Another and more serious one is that a class of criminals is created by the system, and Heaven knows we have too many already! A great moral responsibility rests on those, be they Magistrates or Planters, who lightly send men to jail to herd with hardened criminals. It must not be forgotten that the evil ways of a man do not begin or end with him. His bad example is followed by his children, and he possibly influences a friend or two to cast their lot with him. Their example is followed by others, and so on till, like the ever-increasing circles formed by a stone dropped in a sheet of water, the one life we condemn to a life of crime is the means of influencing ever-increasing circles of those having a like tendency. We who lightly give advances caring or thinking little of the immense harm they do, may well stand appalled at what they had led to. When the season of the Sinhalese New-Year festivities draws nigh, peelers rush heedlessly to every estate that gives advances, and thoughtlessly and regardless of consequences secure as much as each man could get. The bulk of it is spent in gambling and drinking, and after the excitement of both has passed away they realize for the first time that they are virtually slaves and have sold their liberty for the amount of the advances each has taken. Some determine to work themselves free, others to swindle the estate by not turning up for work. These lead a vagabond life till at last they are brought up before the Court on warrant, and for the breach of a civil contract undergo a criminal penalty. They go to jail, and if there be any good traits in their character they are none the worse for contract with criminals; but very often incarceration has a blighting influence on some and they lose all sense of shame. Anyway, whatever be the effect on a man of imprisonment, one who has once been in jail has forfeited what little character he had.

I appeal earnestly to my brother Planters, and more pointedly to Mr. Jardine, who has by his action in connection with Chips assumed their lead, to seriously consider the demoralising effects of giving advances to a body of our employes who do not need them, but with the object of benefiting ourselves by pandering to their weaknesses. Will he not take steps to suppress the practice?—Truly yours, B.

FIG CULTURE.

13th Aug. 1889.

SIR,—The interesting letter over the signature of "Arborator," dated the 28th of June last, gave the public two important facts about fig trees growing in Ceylon: 1st, that the finest variety of fig was imported many years ago from Italy, and 2nd, that the true stock is still to be found in Udapussellawa. Will the gentleman who owns them be so good as to take up the subject and let us know whether they bore fruit, the quality and quantity?

Judging from the numerous wild figs growing around me in this locality, bearing heavily and ripening well, one would think the finest edible kinds would be successful, and yet, who has ever seen a dish of freshly gathered figs in Ceylon? I have not.—Yours faithfully, OLD PLANTER.

ORANGE WINE.

15th August.

DEAR MR. EDITOR,—Will any of your readers kindly give me their experience in the making of orange wine. Where oranges are plentiful it seems a sin to let them fall, and I find they go a long way in the making of marmalade though we are a family rather partial to that conserve.

I have twice attempted orange wine, but with disappointing results, although mine is an old family receipt from which a sparkling wine of excellent quality should result. Perhaps something special has to be done in a tropical climate as regards the fermentation in wood and the period of bringing down, for wine seemed to fail from some such

cause. The clarification was right, also the effervescence. I had a small teak cask made on purpose for it.

Apologizing for troubling, you—I am, yours truly,
PLANTER'S WIFE.

[We trust someone experienced among our readers will come to the rescue. It is a curious fact, as we saw the other day in a book on Ceylon published in the early part of this century, that fairly good wine from grapes was once made at Jaffna. We read:—"Of Roussillon grapes, purple and white, Mr. Bennett introduced the best kinds from Teneriffe and Mauritius. It was found they would grow well only at Jaffna, where even now, [1824] they make wine little inferior to the best Madeira."—Ed.]

THE CINCHONA SYNDICATE SUPPORTED BY THE JAVA PLANTERS' ASSOCIATION.

Soekaboemische Landbouwvereniging Java,
Soekaboemi, 18th August 1889.

SIR,—Baron von Rosenberg's letter together with your editorial concerning a Syndicate of Cinchona planters to regulate the supply of bark to Europe during 1890 and 1891, which you were so kind to send to our President, have been translated by us and read at the ordinary general meeting of the Soekaboemi Agricultural Association on the 14th of this month.

It is not necessary to assure you, that both proposals were met by our members with a hearty adhesion. A resolution was passed to take in this matter no initiative, but to wait, according to Baron von Rosenberg's letter, which steps are to be taken by the Ceylon and British India cinchona planters. We also feel quite sure that a co-operation in this matter will come to a good end and restore the position of the market.

Independent from your editorial and Baron von Rosenberg's letter, the same evening a proposition was accepted, brought forward by one of our members, a cinchona planter, Mr. Burger, in consequence of which our Board of Administration was empowered to take all necessary steps for a petition to H. E. the Governor-General of Netherlands-India, asking that the tremendous crop of Government cinchona bark be diminished to 600,000 half kilogrammes a year, instead of increasing year by year, as now is the case, with 300,000 half kilogrammes. Also for that reason a mission to Java from Ceylon and British India planters, authorized by their fellow planters, would give very satisfactory results, because they could join our petition to H. E., so that our Government became also a partner in the agreement.

The unanimous desire of our members is, to join all steps to be taken for enforcing the market, and we hope sincerely that all other cinchona planters in Java will join us in this good way. Only one objection was made by our President, who pointed out, that on the London auction of 2nd July out of 4,118 bales of bark 1,823 were formed by South American bark. And although they consisted only of Cuprea bark from the imports of 1881-83, it might be that with a higher unit a large quantity of South American bark that has not yet been sold, will be thrown on the market.

Within a fortnight we will also despatch to your address a number of copies of the proceedings of our meeting on the 14th last, with kind request to distribute them among our fellow planters in Ceylon. The same number of copies will be sent to Baron von Rosenberg for distribution in British India.

On the 14th October the last meeting in this year of our Association will take place, and if a mission to Java will become a fact, we shall be very glad to receive her members at that meeting and to offer them the same hospitality as the Ceylon planters offered in 1886 to our President.

We remain, sir, with the highest esteem,
For the Board of Administration of the Soekaboemi Agricultural Association,

G. MUNDT, President.
R. A. EEKHOUT, Secretary

THE FIG TREE IN UDAPUSSELLAWA CEYLON: GOOD SUCCESS.

20th Aug. 1889

DEAR SIR,—Referring to the cultivation of the fig tree in Udapussellawa,—the fig tree was flourishing and bearing fruit on Kirklees estate in 1863. The plant was imported by the late John Armitage from Syria, and all the fig trees which are now thriving in Udapussellawa and probably in Uva are descended from this stock.

They thrive best at an elevation of 3,000 feet but do well up to 5,000 feet. Most of the planters in Udapussellawa are able to put a dish of figs on their table during the hot months of August and September, and a great deal more might be done. In a dry season, the fruit is delicious, quite as luscious as those grown in the Riviera. In a wet year the fruit is deficient in flavour. Your letters on the subject will induce many to extend its cultivation. I shall send you a basket some day next month; but, to be enjoyed, they ought to be pulled first off the tree and eaten with early morning tea. With regard to quantity, I have just counted 140 on one tree, which seems a fair crop.

G. A. D.

FIG CULTURE: No. II.

C. Province, 17th Aug. 1889.

SIR,—In reply to "Old Planter" in your issue of 13th instant, I regret that he has not travelled and seen the Figs that at various times have been exhibited at the Colombo and Kandy Agri-Horticultural Exhibitions. The Kirklees fig trees are famous and produce abundant crops of most delicious fruit, as fine as anything growing in sunny Spain or Italy. Suckers and cuttings from the Kirklees stock grown in Colombo, Kandy, Matale and Dikoya districts have produced fine fruits.

Let "Old Planter" communicate with the worthy manager of Gampaha estate, and I am sure he will receive the necessary information.—Yours,
ARBORATOR.

ORANGE WINE.

August 21st, 1889.

DEAR SIR,—At the request of my wife (after dinner too) I sit down to copy out a receipt for "Planter's Wife." I am sure she will be obliged and very much so should the brew turn out a success: presuming the recipe is faithfully carried out it should make a
"Very Superior Orange Wine."

Ingredients.—90 Seville oranges, 32 lb. of lump sugar, water.

Mode.—Break up the sugar into small pieces, and put it into a dry, sweet 9-gallon cask, placed in a cellar or into other storehouse, where it is intended to be kept. Have ready close to the cask two large pans or wooden keelers, into one of which put the peel of the oranges pared quite thin, and into the other the pulp after the juice has been squeezed from it. Strain the juice through a piece of double muslin, and put into the cask with the sugar. Then pour about 1½ gallon of cold spring water on both the peels and

pulp, let it stand for 24 hours, and then strain it into the cask; add more water to the peels and pulp when this is done, and repeat the same process every day for a week; it should take about a week to fill up the cask. Be careful to apportion the quantity as nearly as possible to seven days, and to stir the contents of the cask each day. On the third day after the cask is full, that is, the tenth day after the commencement of making, the cask may be securely bunged down. This is a very simple and easy method, and the wine made according to it will be pronounced to be most excellent. There is no troublesome boiling, and all fermentation takes place in the cask. When the above directions are attended to, the wine cannot fail to be good. It should be bottled in 8 or 9 months, and will be fit for use in a twelvemonth after time of making.—I am, yours truly,

A PLANTER.

CINNAMON PEELING AND ADVANCES TO PEELERS.

August 22nd, 1889.

DEAR SIR,—I cannot undertake to follow or reply fully to "B.'s" moral essay exposing all the evils which he says follow upon the "immoral and pernicious" system of making a yearly advance to cinnamon peelers. No doubt it has its drawbacks and there may be some objectionable features connected with it, but to charge to it the long array of evils pictured by him is unwarranted. I cannot agree with him that the bulk of the advances are squandered in gambling and drink: there are some who do get rid of their money in this way, and I know a few who as regularly as they receive their weekly advance risk it in gambling. Would "B." suggest that because those men make a bad use of their money that therefore weekly advances should be stopped? We all know that the New Year is a time of feasting and merriment and arraying in new garments; why then should the poor cinnamon peelers, who have very little sunshine in their lives, be debarred from enjoying themselves for a day or two according to their own fashion. I venture to say that on these occasions the proportion of those who become intoxicated is small, while the number of those who indulge in gambling in a mild way is no doubt greater. I am positive that the bulk of the advances made to the men just before their New Year are spent in the purchase of clothes for themselves, their wives and children. "B." would make out that these men are heartless and unfeeling, who without thought for the comfort of their families are only too ready to squander the advance they receive in drinking and gambling. That there are a few such is no reason to condemn a whole section of the community. These men have quite as much natural affection as the generality of natives of the same station in life.

"B." says there is no necessity for making advances; at one time I was inclined to think so too, but I have since altered my opinion. He will I think admit that for the last few years the supply of peelers has not been equal to the demand, and that in consequence there has been much competition for their services. The men are skilled labourers, and, owing to the peculiar nature and circumstances of cinnamon preparation, it is necessary to be certain, as far as possible, that at the right time you will have the command of a certain force of peelers. To leave this an uncertainty would be to make the life of a cinnamon planter a burden to him; as it is, with all the precautions taken, many are the anxious days and sleepless nights he passes lest he should not have a sufficient force to harvest his crop. This anxiety was in my opinion the factor that first compelled the giving of advances;

and as long as the occasion for it lasts, so long will the practice of giving advances last.

Again all peelers are not equally skilful; the cinnamon prepared by some will not realize more than an average of 8d per lb., while that prepared by others will fetch 1s. Am I at great cost of time and trouble to educate my peelers up to my standard, and to have no guarantee that I shall have their services for even one year? Am I to be placed at the risk of my men leaving me for a whim, or of being crimped underhand by some kangany of another estate? No, "B." I am not going to lead any reform in this direction just at present: the time for it is not yet. Is "B." really so simple as to believe that if estate owners do not make advances the system will die out? It is quite a fallacy to think so. How are we to get peelers? Through kanganies of course; and they, to enable them to collect and keep together a sufficient number of men to insure themselves a decent living, will compete with each other. If they do not happen to have the money, they will raise it by a mortgage on their property at probably high interest. To insure their own safety, they will, before advancing a cent to a peeler, get him to sign a bond (*notiwa* as they call it) as a security for the amount advanced, with interest. Now I ask which system is the less objectionable,—that a peeler should receive a small sum from an estate and be responsible to the estate only, or that he should be handed over entirely to the tender mercies of a kangany, who would scarcely ever rest content with the "pound of flesh" his bond entitles him to? Well might the peeler cry out "Save me from my friends."

On the subject of the three years' engagement, I am not aware that on any estate the terms of the agreement are strictly enforced; at any rate they are not here. If within one year a peeler by his labour works off his advance and gives me one month's notice of his wish to leave, so that I may have time to engage another in his place, he is allowed to leave. It depends therefore upon the peeler himself as to whether the agreement shall continue for one year or longer. The object of having it for three years is to protect the estate from loss from those who take advances with a very weak, or no, intention of working them off. While to a certain extent sympathizing with "B." and wishing that we could accomplish our work without advances, I yet cannot see how under present circumstances it is to be done. He should remember that we have not to do with ordinary coolly labor, that can always easily be procured, but with a limited number of skilled workmen, and the temptation to a man who should see his crop ruining before his eyes from want of peelers, to, by some underhand means, crimp some of his neighbour's force would be terrible. "Lead us not into temptation" I pray! As regards encouraging our peelers to undertake other works on the estate I am sure most estates give them every encouragement to do so. They undertake pruning readily, but very few care to do mamoty work, and rather than do it they go long distances to seek for work of a more congenial nature. It is hardly to be wondered at that men whose occupation (except for a few hours every other morning) necessitates their squatting on the ground in a cool well ventilated "waddy" or shed should shirk ten hours a day in the hot sun and sometimes hotter sand beneath their feet. I have briefly replied to "B.'s" letter as he has so pointedly referred to me, and lest if allowed to remain unanswered, the general public should look upon us cinnamon planters as a selfish, callous, slave-holding lot; "Legrees" in a small way!—Yours truly,

WILLIAM JARDINE.

P.S.—I submitted this letter to a cinnamon planter of intelligence and long experience, and he has been good enough to send me some notes. They are so much to the point, and touch upon aspects of the question omitted by me, that they well supplement my hasty remarks: my friend has kindly consented to their being published with my letter.

W. J.

No. 2.

DEAR SIR,—I endorse all you say in reply to "B.'s" letter denouncing the system of advances to peelers. The evils attendant on the practice are magnified and not a word is said as to the mutual benefits derived from the system by planter and peeler. While one man misuses his money, another lays it out to the best advantage, and if drunkards and gamblers are to be found among the peeler class so are there sober and thrifty individuals. During the course of a long experience, on a large estate where the system obtains, I have, of course, met with instances where the funds received as advances were misapplied by the peelers, but I have always found that the great majority of the men spent the best part of the money so received in the purchase of food and clothing for themselves and their families. In a few instances something more substantial is secured as when father and sons jointly invest their advances in buying the rent of a small garden.

But would the deferred payment of wages insure their being put to right uses? A man addicted to drink or gambling would not pause to consider whether it was with wages earned by work or money received in advance that he was indulging in his pet vice; and he would spend the one as readily as the other.

As to the other aspect of the subject, does "B." really mean to deprecate the contract of service entered into by the peelers. What would he substitute in its place to regulate the services of these men? Would he have them come and go according to their own sweet will; working when they liked and idling when they pleased?

If so, how precarious would be the planter's prospect of securing his crop? Even if no outside influence were brought to bear on him by crimping kanganies, self-interest would prompt him to leave an estate as soon as it became exhausted of the best wood. He would be quite intractable and apt to be careless in the performance of his work; for the temporary character of his services would not tend to create in him an interest in any one estate.

My experience leads me to think that the knowledge of the fact that he is legally bound to serve the estate which gives him advances, operates beneficially on the mind of the peeler, and, instead of having a "depressing and demoralizing effect," it stimulates him to liquidate the debt by regular attendance and good work, so that he may become entitled to fresh advances; and the fact that season after season, for the last dozen years or more, the same peelers have regularly received fresh advances and readily renewed their contract is, to my mind, conclusive proof that they do not consider themselves "virtually slaves who have sold their liberty for the amount of the advance each has received."

Without the stimulus of advances the average peeler would I fear do no more work than would bring him enough money to eke out an existence, and where two peelers under advances would suffice, three or perhaps more would be required when under no such obligation to work. ANTI-SLAVERY.

ADVANCES TO CINNAMON PEELERS.

9th August 1889.

DEAR SIR,—I must thank Mr. Jardine for replying to what he is pleased to sneeringly term my "moral essay."

I must at the outset admit that I freely acknowledge that the suppression of the advance system, like every other change, is beset with difficulties; but they are not such as cannot be overcome by combination. I am asked if, because some men make bad use of their weekly advances, therefore these ought to be stopped. Why does Mr. Jardine stop there? He might have gone farther and asked me if I am of opinion that the wages of all those who put them to a wrong use should be withheld. No, Mr. Jardine, there is a broad and well defined distinction between what one earns as his wages and an advance. You cannot honestly withhold the one, while you can the other. I see that one argument for the giving of advances is to allow peelers "enjoying themselves for a day or two according to their own fashion" at the time of the New Year. Does Mr. Jardine show the same solicitude for the enjoyment of all those who happily serve under him? Was that the practice he adopted with his Tamil coolies for their *Tevai* and *Pongol*, or did he by their own wish withhold some of their salary and give them a good round sum to allow them to enjoy themselves "according to their own fashion"? At the time of the Sinhalese New Year is it not customary to square up the accounts of the peelers, after deducting their advances, and immediately after to give them advances? So that you give out with one hand what you have taken in with the other. If, instead of giving them an advance, you gave them their salary, they will be as able to enjoy "themselves according to their own fashion," purchase clothes for their wives and families, and do all Mr. Jardine says is done with advances, only, as is natural, they will be more careful how they spend their hard-earned wages than their advances.

To admit that for the last few years the supply of peelers is not equal to the demand is to admit, either that the acreage under cinnamon during that period has increased, that peelers have diminished in numbers, or that they have taken to other pursuits. I do not admit any of these propositions. All I say is, that owing to the difference in the make of cinnamon, estates want a larger force of peelers now than before, and also that, owing to temporary causes (illness, chiefly fever), there has been a slight diminution of peelers on estates giving advances. Men who are too ill to work on estates to which they are under advances; work readily where they are not indebted.
